All columns to be used in the B-tree index must be of a type for which the default B-tree operator class is available. For details on operator classes, see [Section 11.10](#).

### Examples

Create an in-memory table `blog_views` to store statistics on blog views based on blog post IDs, with the unique B-tree index built upon the first column, in the ascending order:

```
CREATE FOREIGN TABLE blog_views
(
    id int8 NOT NULL,
```

```
    author text,  
    views bigint NOT NULL  
) SERVER in_memory  
OPTIONS (INDICES 'UNIQUE (id)');
```

Define the B-tree index on the `id` and `author` columns, with the `author` values sorted in the ascending order using "`ru_RU`" collation:

```
CREATE FOREIGN TABLE blog_views  
(  
    id int8 NOT NULL,  
    author text,  
    views bigint NOT NULL  
) SERVER in_memory  
OPTIONS (INDICES '(id, author COLLATE "ru_RU" ASC)');
```

### F.25.2.2. Running Queries on In-Memory Tables

Once an in-memory table is created, you can run all the main DML operations on this table: `SELECT`, `INSERT`, `UPDATE`, `DELETE`.

If you use the primary key as the scan qualifier when running queries, a key lookup or range scan is performed. Otherwise, a full index scan is required.

#### Examples

Fill the `blog_views` table with initial zero values for initial ten blog posts:

```
postgres=# INSERT INTO blog_views (SELECT id, 0 FROM generate_series(1, 10) AS id);
```

Increment the view count for a couple of posts and display the result:

```
postgres=# UPDATE blog_views SET views = views + 1 WHERE id = 1;  
UPDATE 1  
postgres=# UPDATE blog_views SET views = views + 1 WHERE id = 1;  
UPDATE 2  
postgres=# UPDATE blog_views SET views = views + 1 WHERE id = 2;  
UPDATE 1  
postgres=# SELECT * FROM blog_views WHERE id = 1 OR id = 2;  
 id | views  
----+-----  
  1 |    2  
  2 |    1  
(2 rows)
```

Check planning and execution costs for a query that only requires a primary key lookup:

```
postgres=# EXPLAIN ANALYZE SELECT * FROM blog_views WHERE id = 1;  
              QUERY PLAN  
-----  
Foreign Scan on blog_views  (cost=0.02..0.03 rows=1 width=16)  
(actual time=0.013..0.014 rows=1 loops=1)  
  Pk conds: (id = 1)  
Planning time: 0.060 ms  
Execution time: 0.035 ms  
(4 rows)
```

Check the costs of calculating the sum of all views, which requires a full index scan:

```
postgres=# EXPLAIN ANALYZE SELECT SUM(views) FROM blog_views;  
              QUERY PLAN  
-----
```

```
Aggregate  (cost=1.62..1.63 rows=1 width=32)
(actual time=0.323..0.323 rows=1 loops=1)
Foreign Scan on blog_views  (cost=0.02..1.30 rows=128 width=8)
(actual time=0.005..0.168 rows=1000 loops=1)
Planning time: 0.113 ms
Execution time: 0.353 ms
(4 rows)
```

### F.25.2.3. Deleting In-Memory Data

When a row is deleted from an in-memory table, data pages are not freed. To free the pages occupied by in-memory tables, you can:

- Delete the table using the `DROP FOREIGN TABLE` command.
- Truncate the table using the `TRUNCATE` command.

`RESTART IDENTITY`, `CONTINUE IDENTITY`, `CASCADE`, and `RESTRICT` options of the `TRUNCATE` command are not supported by in-memory tables.

### F.25.2.4. Writing Data to In-Memory Tables on Hot Standby

In some cases, it can be useful to perform write operations on hot standby servers. For example, suppose you need to collect statistics on queries run on hot standby. Since in-memory tables are writable, you can use them for such purposes.

To set up in-memory tables for write queries on standby, create the required in-memory tables on the primary server as explained in [Section F.25.2.1](#). Once the replication is complete, you can start writing data to these tables on hot standby.

#### Important

If the hot standby server is restarted, all the data stored in its in-memory tables gets truncated. You can continue writing data to the same in-memory tables, but all the previously stored data will be lost.

### F.25.2.5. Getting Statistics on In-Memory Tables

To get statistics on in-memory pages available in your cluster, run the [in\\_memory\\_page\\_stats](#) function, which returns the number of all used and free in-memory pages, as well as the total number of pages allocated for in-memory tables. For example:

```
postgres=# SELECT * FROM in_memory.in_memory_page_stats();
 busy_pages | free_pages | all_pages
-----+-----+-----
      576 |      7616 |      8192
(1 row)
```

### F.25.2.6. Fine-Tuning Memory Settings

#### F.25.2.6.1. Increasing Shared Memory Pool for In-Memory Tables

In-memory tables are stored in a separate shared memory segment. Its size is defined by the `in_memory.shared_pool_size` parameter. By default, this memory segment is limited to 8 MB.

If the data to be stored in in-memory tables exceeds the size of the allocated memory segment, the following error occurs:

```
ERROR: failed to get a new page: shared pool size is exceeded
```

To avoid such issues, you can increase the `in_memory.shared_pool_size` value, or limit the size of the stored data. Changing the shared pool size requires a server restart.

#### F.25.2.6.2. Managing the Undo Log

To enable multi-version concurrency control (MVCC), the `in_memory` module uses the *undo log* — a shared-memory ring buffer that stores the previous versions of data entries and pages. The size of the undo log is defined by the `in_memory.undo_size` parameter and is limited to 1 MB by default. If a buffer overflow occurs before a transaction is complete, the following error is returned:

```
ERROR: failed to add undo record: undo size is exceeded
```

To avoid this issue, you can increase the `in_memory.undo_size` value, or split the transactions into smaller ones.

If the required version of the entry or page has already been overwritten in the undo log when it is accessed for read, the following error occurs:

```
ERROR: snapshot is outdated
```

In this case, you can:

- Increase the `in_memory.undo_size` value. Changing this parameter requires a server restart.
- Ensure that the undo log is not truncated while the snapshot is in use. To achieve this, you can use the `READ COMMITTED` isolation level, or split a complex query into several smaller ones.

### F.25.3. Reference

#### F.25.3.1. Configuration Variables

`in_memory.shared_pool_size` (integer)

Defines the size of the shared memory segment allocated for in-memory tables.

Default: 8MB

`in_memory.undo_size` (integer)

Defines the size of the undo log.

Default: 1MB

#### F.25.3.2. Functions

`in_memory.in_memory_page_stats()`

Displays statistics on pages of in-memory tables:

- `busy_pages` — in-memory pages containing any data.
- `free_pages` — empty in-memory pages. This number includes all the initially allocated pages to which no data has been written yet, as well as the pages from which all data has been deleted.
- `all_pages` — the total number of in-memory pages allocated on this server.

### F.25.4. Authors

Postgres Professional, Moscow, Russia

## F.26. intagg

The `intagg` module provides an integer aggregator and an enumerator. `intagg` is now obsolete, because there are built-in functions that provide a superset of its capabilities. However, the module is still provided as a compatibility wrapper around the built-in functions.

### F.26.1. Functions

The aggregator is an aggregate function `int_array_aggregate(integer)` that produces an integer array containing exactly the integers it is fed. This is a wrapper around `array_agg`, which does the same thing for any array type.

The enumerator is a function `int_array_enum(integer[])` that returns `setof integer`. It is essentially the reverse operation of the aggregator: given an array of integers, expand it into a set of rows. This is a wrapper around `unnest`, which does the same thing for any array type.

## F.26.2. Sample Uses

Many database systems have the notion of a one to many table. Such a table usually sits between two indexed tables, for example:

```
CREATE TABLE left (id INT PRIMARY KEY, ...);
CREATE TABLE right (id INT PRIMARY KEY, ...);
CREATE TABLE one_to_many(left INT REFERENCES left, right INT REFERENCES right);
```

It is typically used like this:

```
SELECT right.* from right JOIN one_to_many ON (right.id = one_to_many.right)
WHERE one_to_many.left = item;
```

This will return all the items in the right hand table for an entry in the left hand table. This is a very common construct in SQL.

Now, this methodology can be cumbersome with a very large number of entries in the `one_to_many` table. Often, a join like this would result in an index scan and a fetch for each right hand entry in the table for a particular left hand entry. If you have a very dynamic system, there is not much you can do. However, if you have some data which is fairly static, you can create a summary table with the aggregator.

```
CREATE TABLE summary AS
SELECT left, int_array_aggregate(right) AS right
FROM one_to_many
GROUP BY left;
```

This will create a table with one row per left item, and an array of right items. Now this is pretty useless without some way of using the array; that's why there is an array enumerator. You can do

```
SELECT left, int_array_enum(right) FROM summary WHERE left = item;
```

The above query using `int_array_enum` produces the same results as

```
SELECT left, right FROM one_to_many WHERE left = item;
```

The difference is that the query against the summary table has to get only one row from the table, whereas the direct query against `one_to_many` must index scan and fetch a row for each entry.

On one system, an `EXPLAIN` showed a query with a cost of 8488 was reduced to a cost of 329. The original query was a join involving the `one_to_many` table, which was replaced by:

```
SELECT right, count(right) FROM
( SELECT left, int_array_enum(right) AS right
  FROM summary JOIN (SELECT left FROM left_table WHERE left = item) AS lefts
    ON (summary.left = lefts.left)
) AS list
GROUP BY right
ORDER BY count DESC;
```

## F.27. intarray

The `intarray` module provides a number of useful functions and operators for manipulating null-free arrays of integers. There is also support for indexed searches using some of the operators.

All of these operations will throw an error if a supplied array contains any `NULL` elements.

Many of these operations are only sensible for one-dimensional arrays. Although they will accept input arrays of more dimensions, the data is treated as though it were a linear array in storage order.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

## F.27.1. intarray Functions and Operators

The functions provided by the `intarray` module are shown in [Table F.20](#), the operators in [Table F.21](#).

**Table F.20. intarray Functions**

| Function<br>Description<br>Example(s)                                                                                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>icount ( integer[] ) → integer</code><br>Returns the number of elements in the array.<br><code>icount ('{1,2,3}'::integer[]) → 3</code>                                                                                                                         |
| <code>sort ( integer[], dir text ) → integer[]</code><br>Sorts the array in either ascending or descending order. <i>dir</i> must be <code>asc</code> or <code>desc</code> .<br><code>sort ('{1,3,2}'::integer[], 'desc') → {3,2,1}</code>                            |
| <code>sort ( integer[] ) → integer[]</code><br><code>sort_asc ( integer[] ) → integer[]</code><br>Sorts in ascending order.<br><code>sort(array[11,77,44]) → {11,44,77}</code>                                                                                        |
| <code>sort_desc ( integer[] ) → integer[]</code><br>Sorts in descending order.<br><code>sort_desc(array[11,77,44]) → {77,44,11}</code>                                                                                                                                |
| <code>uniq ( integer[] ) → integer[]</code><br>Removes adjacent duplicates. Often used with <code>sort</code> to remove all duplicates.<br><code>uniq ('{1,2,2,3,1,1}'::integer[]) → {1,2,3,1}</code><br><code>uniq(sort ('{1,2,3,2,1}'::integer[])) → {1,2,3}</code> |
| <code>idx ( integer[], item integer ) → integer</code><br>Returns index of the first array element matching <i>item</i> , or 0 if no match.<br><code>idx(array[11,22,33,22,11], 22) → 2</code>                                                                        |
| <code>subarray ( integer[], start integer, len integer ) → integer[]</code><br>Extracts the portion of the array starting at position <i>start</i> , with <i>len</i> elements.<br><code>subarray ('{1,2,3,2,1}'::integer[], 2, 3) → {2,3,2}</code>                    |
| <code>subarray ( integer[], start integer ) → integer[]</code><br>Extracts the portion of the array starting at position <i>start</i> .<br><code>subarray ('{1,2,3,2,1}'::integer[], 2) → {2,3,2,1}</code>                                                            |
| <code>intset ( integer ) → integer[]</code><br>Makes a single-element array.<br><code>intset(42) → {42}</code>                                                                                                                                                        |

**Table F.21. intarray Operators**

| Operator<br>Description                                                                                           |
|-------------------------------------------------------------------------------------------------------------------|
| <code>integer[] &amp;&amp; integer[] → boolean</code><br>Do arrays overlap (have at least one element in common)? |
| <code>integer[] @&gt; integer[] → boolean</code><br>Does left array contain right array?                          |
| <code>integer[] &lt;@ integer[] → boolean</code><br>Is left array contained in right array?                       |

| Operator                                           | Description                                                                                                                  |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <code># integer[] → integer</code>                 | Returns the number of elements in the array.                                                                                 |
| <code>integer[] # integer → integer</code>         | Returns index of the first array element matching the right argument, or 0 if no match. (Same as <code>idx</code> function.) |
| <code>integer[] + integer → integer[]</code>       | Adds element to end of array.                                                                                                |
| <code>integer[] + integer[] → integer[]</code>     | Concatenates the arrays.                                                                                                     |
| <code>integer[] - integer → integer[]</code>       | Removes entries matching the right argument from the array.                                                                  |
| <code>integer[] - integer[] → integer[]</code>     | Removes elements of the right array from the left array.                                                                     |
| <code>integer[]   integer → integer[]</code>       | Computes the union of the arguments.                                                                                         |
| <code>integer[]   integer[] → integer[]</code>     | Computes the union of the arguments.                                                                                         |
| <code>integer[] &amp; integer[] → integer[]</code> | Computes the intersection of the arguments.                                                                                  |
| <code>integer[] @@ query_int → boolean</code>      | Does array satisfy query? (see below)                                                                                        |
| <code>query_int ~~ integer[] → boolean</code>      | Does array satisfy query? (commutator of @@)                                                                                 |

The operators `&&`, `@>` and `<@` are equivalent to Postgres Pro's built-in operators of the same names, except that they work only on integer arrays that do not contain nulls, while the built-in operators work for any array type. This restriction makes them faster than the built-in operators in many cases.

The `@@` and `~~` operators test whether an array satisfies a *query*, which is expressed as a value of a specialized data type `query_int`. A *query* consists of integer values that are checked against the elements of the array, possibly combined using the operators `&` (AND), `|` (OR), and `!` (NOT). Parentheses can be used as needed. For example, the query `1 & (2 | 3)` matches arrays that contain 1 and also contain either 2 or 3.

## F.27.2. Index Support

`intarray` provides index support for the `&&`, `@>`, and `@@` operators, as well as regular array equality.

Two parameterized GiST index operator classes are provided: `gist__int_ops` (used by default) is suitable for small- to medium-size data sets, while `gist__intbig_ops` uses a larger signature and is more suitable for indexing large data sets (i.e., columns containing a large number of distinct array values). The implementation uses an RD-tree data structure with built-in lossy compression.

`gist__int_ops` approximates an integer set as an array of integer ranges. Its optional integer parameter `numranges` determines the maximum number of ranges in one index key. The default value of `numranges` is 100. Valid values are between 1 and 253. Using larger arrays as GiST index keys leads to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

`gist__intbig_ops` approximates an integer set as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 16 bytes. Valid values

of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

There is also a non-default GIN operator class `gin__int_ops`, which supports these operators as well as `<@`.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

### F.27.3. Example

```
-- a message can be in one or more "sections"
CREATE TABLE message (mid INT PRIMARY KEY, sections INT[], ...);

-- create specialized index with signature length of 32 bytes
CREATE INDEX message_rdtree_idx ON message USING GIST (sections gist__intbig_ops
(siglen = 32));

-- select messages in section 1 OR 2 - OVERLAP operator
SELECT message.mid FROM message WHERE message.sections && '{1,2}';

-- select messages in sections 1 AND 2 - CONTAINS operator
SELECT message.mid FROM message WHERE message.sections @> '{1,2}';

-- the same, using QUERY operator
SELECT message.mid FROM message WHERE message.sections @@ '1&2'::query_int;
```

### F.27.4. Authors

All work was done by Teodor Sigaev (<teodor@sigaev.ru>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megera/postgres/gist/> for additional information. Andrey Oktyabrski did a great work on adding new functions and operations.

## F.28. isn

The `isn` module provides data types for the following international product numbering standards: EAN13, UPC, ISBN (books), ISMN (music), and ISSN (serials). Numbers are validated on input according to a hard-coded list of prefixes; this list of prefixes is also used to hyphenate numbers on output. Since new prefixes are assigned from time to time, the list of prefixes may be out of date. It is hoped that a future version of this module will obtain the prefix list from one or more tables that can be easily updated by users as needed; however, at present, the list can only be updated by modifying the source code and recompiling. Alternatively, prefix validation and hyphenation support may be dropped from a future version of this module.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.28.1. Data Types

Table F.22 shows the data types provided by the `isn` module.

**Table F.22. isn Data Types**

| Data Type | Description                                                                         |
|-----------|-------------------------------------------------------------------------------------|
| EAN13     | European Article Numbers, always displayed in the EAN13 display format              |
| ISBN13    | International Standard Book Numbers to be displayed in the new EAN13 display format |

| Data Type | Description                                                                           |
|-----------|---------------------------------------------------------------------------------------|
| ISMN13    | International Standard Music Numbers to be displayed in the new EAN13 display format  |
| ISSN13    | International Standard Serial Numbers to be displayed in the new EAN13 display format |
| ISBN      | International Standard Book Numbers to be displayed in the old short display format   |
| ISMN      | International Standard Music Numbers to be displayed in the old short display format  |
| ISSN      | International Standard Serial Numbers to be displayed in the old short display format |
| UPC       | Universal Product Codes                                                               |

Some notes:

1. ISBN13, ISMN13, ISSN13 numbers are all EAN13 numbers.
2. EAN13 numbers aren't always ISBN13, ISMN13 or ISSN13 (some are).
3. Some ISBN13 numbers can be displayed as ISBN.
4. Some ISMN13 numbers can be displayed as ISMN.
5. Some ISSN13 numbers can be displayed as ISSN.
6. UPC numbers are a subset of the EAN13 numbers (they are basically EAN13 without the first 0 digit).
7. All UPC, ISBN, ISMN and ISSN numbers can be represented as EAN13 numbers.

Internally, all these types use the same representation (a 64-bit integer), and all are interchangeable. Multiple types are provided to control display formatting and to permit tighter validity checking of input that is supposed to denote one particular type of number.

The `ISBN`, `ISMN`, and `ISSN` types will display the short version of the number (ISxN 10) whenever it's possible, and will show ISxN 13 format for numbers that do not fit in the short version. The `EAN13`, `ISBN13`, `ISMN13` and `ISSN13` types will always display the long version of the ISxN (EAN13).

## F.28.2. Casts

The `isn` module provides the following pairs of type casts:

- `ISBN13 <=> EAN13`
- `ISMN13 <=> EAN13`
- `ISSN13 <=> EAN13`
- `ISBN <=> EAN13`
- `ISMN <=> EAN13`
- `ISSN <=> EAN13`
- `UPC <=> EAN13`
- `ISBN <=> ISBN13`
- `ISMN <=> ISMN13`
- `ISSN <=> ISSN13`

When casting from `EAN13` to another type, there is a run-time check that the value is within the domain of the other type, and an error is thrown if not. The other casts are simply relabelings that will always succeed.

## F.28.3. Functions and Operators

The `isn` module provides the standard comparison operators, plus B-tree and hash indexing support for all these data types. In addition there are several specialized functions; shown in [Table F.23](#). In this table, `isn` means any one of the module's data types.

**Table F.23. `isn` Functions**

| Function                                  | Description                                            |
|-------------------------------------------|--------------------------------------------------------|
| <code>isn_weak (boolean) → boolean</code> | Sets the weak input mode, and returns new setting.     |
| <code>isn_weak () → boolean</code>        | Returns the current status of the weak mode.           |
| <code>make_valid (isn) → isn</code>       | Validates an invalid number (clears the invalid flag). |
| <code>is_valid (isn) → boolean</code>     | Checks for the presence of the invalid flag.           |

*Weak* mode is used to be able to insert invalid data into a table. Invalid means the check digit is wrong, not that there are missing numbers.

Why would you want to use the weak mode? Well, it could be that you have a huge collection of ISBN numbers, and that there are so many of them that for weird reasons some have the wrong check digit (perhaps the numbers were scanned from a printed list and the OCR got the numbers wrong, perhaps the numbers were manually captured... who knows). Anyway, the point is you might want to clean the mess up, but you still want to be able to have all the numbers in your database and maybe use an external tool to locate the invalid numbers in the database so you can verify the information and validate it more easily; so for example you'd want to select all the invalid numbers in the table.

When you insert invalid numbers in a table using the weak mode, the number will be inserted with the corrected check digit, but it will be displayed with an exclamation mark (!) at the end, for example 0-11-000322-5!. This invalid marker can be checked with the `is_valid` function and cleared with the `make_valid` function.

You can also force the insertion of invalid numbers even when not in the weak mode, by appending the `!` character at the end of the number.

Another special feature is that during input, you can write `?` in place of the check digit, and the correct check digit will be inserted automatically.

## F.28.4. Examples

```
--Using the types directly:
SELECT isbn('978-0-393-04002-9');
SELECT isbn13('0901690546');
SELECT issn('1436-4522');

--Casting types:
-- note that you can only cast from ean13 to another type when the
-- number would be valid in the realm of the target type;
-- thus, the following will NOT work: select isbn(ean13('0220356483481'));
-- but these will:
SELECT upc(ean13('0220356483481'));
SELECT ean13(upc('220356483481'));

--Create a table with a single column to hold ISBN numbers:
```

```
CREATE TABLE test (id isbn);
INSERT INTO test VALUES('9780393040029');

--Automatically calculate check digits (observe the '?'):
INSERT INTO test VALUES('220500896?');
INSERT INTO test VALUES('978055215372?');

SELECT issn('3251231?');
SELECT ismn('979047213542?');

--Using the weak mode:
SELECT isn_weak(true);
INSERT INTO test VALUES('978-0-11-000533-4');
INSERT INTO test VALUES('9780141219307');
INSERT INTO test VALUES('2-205-00876-X');
SELECT isn_weak(false);

SELECT id FROM test WHERE NOT is_valid(id);
UPDATE test SET id = make_valid(id) WHERE id = '2-205-00876-X!';

SELECT * FROM test;

SELECT isbn13(id) FROM test;
```

## F.28.5. Bibliography

The information to implement this module was collected from several sites, including:

- <https://www.isbn-international.org/>
- <https://www.issn.org/>
- <https://www.ismn-international.org/>
- <https://www.wikipedia.org/>

The prefixes used for hyphenation were also compiled from:

- <https://www.gs1.org/standards/id-keys>
- [https://en.wikipedia.org/wiki/List\\_of\\_ISBN\\_identifier\\_groups](https://en.wikipedia.org/wiki/List_of_ISBN_identifier_groups)
- <https://www.isbn-international.org/content/isbn-users-manual/29>
- [https://en.wikipedia.org/wiki/International\\_Standard\\_Music\\_Number](https://en.wikipedia.org/wiki/International_Standard_Music_Number)
- <https://www.ismn-international.org/ranges/tools>

Care was taken during the creation of the algorithms and they were meticulously verified against the suggested algorithms in the official ISBN, ISMN, ISSN User Manuals.

## F.28.6. Author

Germán Méndez Bravo (Kronuz), 2004–2006

This module was inspired by Garrett A. Wollman's `isbn_issn` code.

## F.29. jquery

jQuery is a language to query `jsonb` data type. Its primary goal is to provide an additional functionality for `jsonb`, such as a simple and effective way for search in nested objects and arrays, as well as additional comparison operators with index support.

jQuery is implemented by means of a `jquery` data type (similar to `tsquery`) and the `@@` match operator for `jsonb`.

## F.29.1. Installation

Postgres Pro Enterprise distribution includes `jsquery` as a contrib module. Once you complete Postgres Pro Enterprise installation, create the `jsquery` extension, as follows:

```
CREATE EXTENSION jsquery;
```

## F.29.2. JSON query language

`JsQuery` extension contains `jsquery` datatype which represents whole JSON query as a single value (like `tsquery` does for fulltext search). The query is an expression on JSON-document values.

Simple expression is specified as *path binary\_operator value* or *path unary\_operator*. See the following examples.

- `x = "abc"` - value of key "x" is equal to "abc";
- `$ @> [4, 5, "zzz"]` - the JSON document is an array containing values 4, 5 and "zzz";
- `"abc xyz" >= 10` - value of key "abc xyz" is greater than or equal to 10;
- `volume IS NUMERIC` - type of key "volume" is numeric.
- `$ = true` - the whole JSON document is just a true.
- `similar_ids.@# > 5` - `similar_ids` is an array or object of length greater than 5;
- `similar_product_ids.# = "0684824396"` - array `similar_product_ids` contains string "0684824396".
- `*.color = "red"` - there is object somewhere which key "color" has value "red".
- `foo = *` - key "foo" exists in object.

Path selects set of JSON values to be checked using given operators. In the simplest case, path is just a key name. In general, path is key names and placeholders combined by dot signs. Path can use the following placeholders:

- `#` - any index of array;
- `#N` - Nth index of array;
- `%` - any key of object;
- `*` - any sequence of array indexes and object keys;
- `@#` - length of array or object, could be only used as last component of path;
- `$` - the whole JSON document as single value, could be only the whole path.

Expression is true when operator is true against at least one value selected by path.

Key names could be given either with or without double quotes. Key names without double quotes shouldn't contain spaces, start with number, or concur with `jsquery` keyword.

The supported binary operators are:

- Equality operator: `=`;
- Numeric comparison operators: `>`, `>=`, `<`, `<=`;
- Search in the list of scalar values using `IN` operator;
- Array comparison operators: `&&` (overlap), `@>` (contains), `<@` (contained in).
- Filtering operator: `~~`. Taking `jsonb` data as the left operand and a `jsquery` expression as the right operand, this operator checks that `jsonb` data contains any entries that satisfy the condition provided in a `jsquery` expression and returns an array of such entries, if any.

The supported unary operators are:

- Check for existence operator: `= *`;
- Check for type operators: `IS ARRAY`, `IS NUMERIC`, `IS OBJECT`, `IS STRING` and `IS BOOLEAN`.

Expressions could be complex. Complex expression is a set of expressions combined by logical operators (`AND`, `OR`, `NOT`) and grouped using parentheses.

Examples of complex expressions are given below.

- `a = 1 AND (b = 2 OR c = 3) AND NOT d = 1`
- `x.% = true OR x.# = true`

Prefix expressions are expressions given in the form `path (subexpression)`. In this case `path` selects JSON values to be checked using given `subexpression`. Check results are aggregated in the same way as in simple expressions.

- `#(a = 1 AND b = 2)` - an array contains an element where the `a` key is 1 and the `b` key is 2
- `%($ >= 10 AND $ <= 20)` - an object contains a key with a value between 10 and 20

Path also could contain the following special placeholders with "every" semantics:

- `#:` - every index of array;
- `%:` - every key of object;
- `*` - every sequence of array indexes and object keys.

Consider the following example.

```
%.#:($ >= 0 AND $ <= 1)
```

This example could be read as follows: there is at least one key for which the value is an array of numerics between 0 and 1.

We can rewrite this example in the following form with extra parentheses.

```
%(#:($ >= 0 AND $ <= 1))
```

The first placeholder `%` checks that expression in parentheses is true for at least one value in object. The second placeholder `#:` checks that the value is an array and all its elements satisfy expressions in parentheses.

We can rewrite this example without `#:` placeholder as follows.

```
%(NOT #(NOT ($ >= 0 AND $ <= 1)) AND $ IS ARRAY)
```

In this example we transform assertion that every element of array satisfies some condition to assertion that there is no one element which doesn't satisfy the same condition.

Some examples of using paths are given below.

- `numbers.#: IS NUMERIC` - every element of "numbers" array is numeric.
- `*:($ IS OBJECT OR $ IS BOOLEAN)` - JSON is a structure of nested objects with booleans as leaf values.
- `#:.%:($ >= 0 AND $ <= 1)` - each element of array is object containing only numeric values between 0 and 1.
- `documents.#:.% = *` - "documents" is an array of objects containing at least one key.
- `%.#: ($ IS STRING)` - JSON object contains at least one array of strings.
- `%.% = true` - at least one array element is an object that contains at least one "true" value.

Usage of path operators and parentheses needs some explanation. When same path operators are used multiple times they may refer to different values while you can refer to the same value multiple times by using parentheses and `$` operator. See the following examples.

- `# < 10 AND # > 20` - there is an element less than 10 and another element greater than 20.
- `#$ < 10 AND $ > 20` - there is an element that is both less than 10 and greater than 20 (impossible).
- `$( $ >= 10 AND $ <= 20 )` - there is an element between 10 and 20.
- `# >= 10 AND # <= 20` - there is an element greater than or equal to 10 and another element less than or equal to 20. The query can be satisfied by an array with no elements between 10 and 20, for instance `[0,30]`.

Same rules apply when you search inside objects and branchy structures.

Type checking operators and "every" placeholders are useful for document schema validation. JQuery matching operator `@@` is immutable and can be used in CHECK constraint. See the following example.

```
CREATE TABLE js (  
    id serial,  
    data jsonb,  
    CHECK (data @@ '  
        name IS STRING AND  
        similar_ids.#: IS NUMERIC AND  
        points.#:(x IS NUMERIC AND y IS NUMERIC) '::jsquery));
```

In this example check constraint validates that in "data" jsonb column: value of "name" key is string, value of "similar\_ids" key is array of numerics, value of "points" key is array of objects which contain numeric values in "x" and "y" keys.

See our [pgconf.eu presentation](#) for more examples.

## F.29.3. GIN indexes

JsQuery extension contains two operator classes (opclasses) for GIN which provide different kinds of query optimization.

- `jsonb_path_value_ops`
- `jsonb_value_path_ops`

In each of two GIN opclasses jsonb documents are decomposed into entries. Each entry is associated with a particular value and its path. Difference between opclasses is in the entry representation, comparison, and usage for search optimization.

For example, jsonb document `{ "a": [{ "b": "xyz", "c": true }, 10], "d": { "e": [7, false] } }` would be decomposed into the following entries:

- `"a".#."b"."xyz"`
- `"a".#."c".true`
- `"a".#.10`
- `"d"."e".#.7`
- `"d"."e".#.false`

Since JsQuery doesn't support search in a particular array index, we consider all array elements to be equivalent. Thus, each array element is marked with the same # sign in the path.

Major problem in the entries representation is its size. In the given example key "a" is presented three times. In the large branchy documents with long keys size of naive entries representation becomes unreasonable. Both opclasses address this issue but in a slightly different way.

### F.29.3.1. `jsonb_path_value_ops`

`jsonb_path_value_ops` represents entry as pair of path hash and value. The following pseudocode illustrates it.

```
(hash(path_item_1.path_item_2. ... .path_item_n); value)
```

In comparison of entries path hash is the higher part of entry and value is its lower part. This determines the features of this opclass. Since path is hashed and it is higher part of entry we need to know the full path to the value in order to use it for search. However, once path is specified we can use both exact and range searches very efficiently.

### F.29.3.2. `jsonb_value_path_ops`

`jsonb_value_path_ops` represents entry as pair of value and bloom filter of path.

```
(value; bloom(path_item_1) | bloom(path_item_2) | ... | bloom(path_item_n))
```

In comparison of entries value is the higher part of entry and bloom filter of path is its lower part. This determines the features of this opclass. Since value is the higher part of entry we can perform only exact value search efficiently. Range value search is possible as well but we would have to filter all

the different paths where matching values occur. Bloom filter over path items allows index usage for conditions containing % and \* in their paths.

### F.29.3.3. Query optimization

JsQuery opclasses perform complex query optimization. Thus it's valuable for developer or administrator to see the result of such optimization. Unfortunately, opclasses aren't allowed to do any custom output to the EXPLAIN. That's why JsQuery provides the following functions which allows to see how particular opclass optimizes given query.

- `gin_debug_query_path_value(jsquery)` - for `jsonb_path_value_ops`
- `gin_debug_query_value_path(jsquery)` - for `jsonb_value_path_ops`

Result of these functions is a textual representation of query tree which leaves are GIN search entries. The following examples show different results of query optimization by different opclasses.

```
# SELECT gin_debug_query_path_value('x = 1 AND (*.y = 1 OR y = 2)');
gin_debug_query_path_value
-----
x = 1 , entry 0          +

# SELECT gin_debug_query_value_path('x = 1 AND (*.y = 1 OR y = 2)');
gin_debug_query_value_path
-----
AND                        +
  x = 1 , entry 0          +
  OR                        +
    *.y = 1 , entry 1      +
    y = 2 , entry 2        +
```

Unfortunately, jsonb has no statistics yet. That's why JsQuery optimizer has to do imperative decision while selecting conditions to be evaluated using index. This decision is made by assumption that some condition types are less selective than others. Optimizer divides conditions into the following selectivity class (listed by descending of selectivity).

1. Equality ( $x = c$ )
2. Range ( $c1 < x < c2$ )
3. Inequality ( $x > c$ )
4. Is ( $x$  is type)
5. Any ( $x = *$ )

Optimizer evades index evaluation of less selective conditions when possible. For example, in the `x = 1 AND y > 0` query `x = 1` is assumed to be more selective than `y > 0`. That's why index isn't used for evaluation of `y > 0`.

```
# SELECT gin_debug_query_path_value('x = 1 AND y > 0');
gin_debug_query_path_value
-----
x = 1 , entry 0          +
```

With lack of statistics decisions made by optimizer can be inaccurate. That's why JsQuery supports hints. Comments `/*-- index */` and `/*-- noindex */` placed in the conditions force optimizer to use and not to use index correspondingly.

```
SELECT gin_debug_query_path_value('x = 1 AND y /*-- index */ > 0');
gin_debug_query_path_value
-----
AND                        +
  x = 1 , entry 0          +
  y > 0 , entry 1          +

SELECT gin_debug_query_path_value('x /*-- noindex */ = 1 AND y > 0');
```

gin\_debug\_query\_path\_value

-----  
y > 0 , entry 0 +

## F.29.5. Credits

Development is sponsored by [Wargaming.net](http://Wargaming.net).

## F.30. lo

The `lo` module provides support for managing Large Objects (also called LOs or BLOBs). This includes a data type `lo` and a trigger `lo_manage`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.30.1. Rationale

One of the problems with the JDBC driver (and this affects the ODBC driver also), is that the specification assumes that references to BLOBs (Binary Large Objects) are stored within a table, and if that entry is changed, the associated BLOB is deleted from the database.

As Postgres Pro stands, this doesn't occur. Large objects are treated as objects in their own right; a table entry can reference a large object by OID, but there can be multiple table entries referencing the same large object OID, so the system doesn't delete the large object just because you change or remove one such entry.

Now this is fine for Postgres Pro-specific applications, but standard code using JDBC or ODBC won't delete the objects, resulting in orphan objects — objects that are not referenced by anything, and simply occupy disk space.

The `lo` module allows fixing this by attaching a trigger to tables that contain LO reference columns. The trigger essentially just does a `lo_unlink` whenever you delete or modify a value referencing a large object. When you use this trigger, you are assuming that there is only one database reference to any large object that is referenced in a trigger-controlled column!

The module also provides a data type `lo`, which is really just a domain of the `oid` type. This is useful for differentiating database columns that hold large object references from those that are OIDs of other things. You don't have to use the `lo` type to use the trigger, but it may be convenient to use it to keep track of which columns in your database represent large objects that you are managing with the trigger. It is also rumored that the ODBC driver gets confused if you don't use `lo` for BLOB columns.

### F.30.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE image (title text, raster lo);
```

```
CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON image  
FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
```

For each column that will contain unique references to large objects, create a `BEFORE UPDATE OR DELETE` trigger, and give the column name as the sole trigger argument. You can also restrict the trigger to only execute on updates to the column by using `BEFORE UPDATE OF column_name`. If you need multiple `lo` columns in the same table, create a separate trigger for each one, remembering to give a different name to each trigger on the same table.

### F.30.3. Limitations

- Dropping a table will still orphan any objects it contains, as the trigger is not executed. You can avoid this by preceding the `DROP TABLE` with `DELETE FROM table`.

`TRUNCATE` has the same hazard.

If you already have, or suspect you have, orphaned large objects, see the [vacuumlo](#) module to help you clean them up. It's a good idea to run `vacuumlo` occasionally as a back-stop to the `lo_manage` trigger.

- Some frontends may create their own tables, and will not create the associated trigger(s). Also, users may not remember (or know) to create the triggers.

Peter Mount <[peter@retep.org.uk](mailto:peter@retep.org.uk)>

## F.31. ltree

This module implements a data type `ltree` for representing labels of data stored in a hierarchical tree-like structure. Extensive facilities for searching through label trees are provided.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.31.1. Definitions

A *label* is a sequence of alphanumeric characters and underscores (for example, in C locale the characters `A-Za-z0-9_` are allowed). Labels must be less than 256 characters long.

Examples: `42`, `Personal_Services`

A *label path* is a sequence of zero or more labels separated by dots, for example `L1.L2.L3`, representing a path from the root of a hierarchical tree to a particular node. The length of a label path cannot exceed 65535 labels.

Example: `Top.Countries.Europe.Russia`

The `ltree` module provides several data types:

- `ltree` stores a label path.
- `lquery` represents a regular-expression-like pattern for matching `ltree` values. A simple word matches that label within a path. A star symbol (`*`) matches zero or more labels. These can be joined with dots to form a pattern that must match the whole label path. For example:

|                      |                                                            |
|----------------------|------------------------------------------------------------|
| <code>foo</code>     | Match the exact label path <code>foo</code>                |
| <code>*.foo.*</code> | Match any label path containing the label <code>foo</code> |
| <code>*.foo</code>   | Match any label path whose last label is <code>foo</code>  |

Both star symbols and simple words can be quantified to restrict how many labels they can match:

|                       |                                                                                                |
|-----------------------|------------------------------------------------------------------------------------------------|
| <code>{n}</code>      | Match exactly <code>n</code> labels                                                            |
| <code>{n,}</code>     | Match at least <code>n</code> labels                                                           |
| <code>{n,m}</code>    | Match at least <code>n</code> but not more than <code>m</code> labels                          |
| <code>{,m}</code>     | Match at most <code>m</code> labels – same as <code>{0,m}</code>                               |
| <code>foo{n,m}</code> | Match at least <code>n</code> but not more than <code>m</code> occurrences of <code>foo</code> |
| <code>foo{,}</code>   | Match any number of occurrences of <code>foo</code> , including zero                           |

In the absence of any explicit quantifier, the default for a star symbol is to match any number of labels (that is, `{,}`) while the default for a non-star item is to match exactly once (that is, `{1}`).

There are several modifiers that can be put at the end of a non-star `lquery` item to make it match more than just the exact match:

@           Match case-insensitively, for example `a@` matches `A`  
\*           Match any label with this prefix, for example `foo*` matches `foobar`  
%           Match initial underscore-separated words

The behavior of `%` is a bit complicated. It tries to match words rather than the entire label. For example `foo_bar%` matches `foo_bar_baz` but not `foo_barbaz`. If combined with `*`, prefix matching applies to each word separately, for example `foo_bar%*` matches `foo1_bar2_baz` but not `foo1_br2_baz`.

Also, you can write several possibly-modified non-star items separated with `|` (OR) to match any of those items, and you can put `!` (NOT) at the start of a non-star group to match any label that doesn't match any of the alternatives. A quantifier, if any, goes at the end of the group; it means some number of matches for the group as a whole (that is, some number of labels matching or not matching any of the alternatives).

Here's an annotated example of `lquery`:

```
Top.*{0,2}.sport*@.!football|tennis{1,}.Russ*|Spain
a.  b.      c.      d.                  e.
```

This query will match any label path that:

- a. begins with the label `Top`
  - b. and next has zero to two labels before
  - c. a label beginning with the case-insensitive prefix `sport`
  - d. then has one or more labels, none of which match `football` nor `tennis`
  - e. and then ends with a label beginning with `Russ` or exactly matching `Spain`.
- `ltxquery` represents a full-text-search-like pattern for matching `ltree` values. An `ltxquery` value contains words, possibly with the modifiers `@`, `*`, `%` at the end; the modifiers have the same meanings as in `lquery`. Words can be combined with `&` (AND), `|` (OR), `!` (NOT), and parentheses. The key difference from `lquery` is that `ltxquery` matches words without regard to their position in the label path.

Here's an example `ltxquery`:

```
Europe & Russia*@ & !Transportation
```

This will match paths that contain the label `Europe` and any label beginning with `Russia` (case-insensitive), but not paths containing the label `Transportation`. The location of these words within the path is not important. Also, when `%` is used, the word can be matched to any underscore-separated word within a label, regardless of position.

Note: `ltxquery` allows whitespace between symbols, but `ltree` and `lquery` do not.

## F.31.2. Operators and Functions

Type `ltree` has the usual comparison operators `=`, `<>`, `<`, `>`, `<=`, `>=`. Comparison sorts in the order of a tree traversal, with the children of a node sorted by label text. In addition, the specialized operators shown in [Table F.24](#) are available.

**Table F.24. `ltree` Operators**

| Operator                       | Description            |
|--------------------------------|------------------------|
| <code>ltree @&gt; ltree</code> | <code>→ boolean</code> |

| Operator                                                                                 | Description                                                                             |
|------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
|                                                                                          | Is left argument an ancestor of right (or equal)?                                       |
| <code>ltree &lt;@ ltree → boolean</code>                                                 | Is left argument a descendant of right (or equal)?                                      |
| <code>ltree ~ lquery → boolean</code><br><code>lquery ~ ltree → boolean</code>           | Does <code>ltree</code> match <code>lquery</code> ?                                     |
| <code>ltree ? lquery[] → boolean</code><br><code>lquery[] ? ltree → boolean</code>       | Does <code>ltree</code> match any <code>lquery</code> in array?                         |
| <code>ltree @ ltxtquery → boolean</code><br><code>ltxtquery @ ltree → boolean</code>     | Does <code>ltree</code> match <code>ltxtquery</code> ?                                  |
| <code>ltree    ltree → ltree</code>                                                      | Concatenates <code>ltree</code> paths.                                                  |
| <code>ltree    text → ltree</code><br><code>text    ltree → ltree</code>                 | Converts <code>text</code> to <code>ltree</code> and concatenates.                      |
| <code>ltree[] @&gt; ltree → boolean</code><br><code>ltree &lt;@ ltree[] → boolean</code> | Does array contain an ancestor of <code>ltree</code> ?                                  |
| <code>ltree[] &lt;@ ltree → boolean</code><br><code>ltree @&gt; ltree[] → boolean</code> | Does array contain a descendant of <code>ltree</code> ?                                 |
| <code>ltree[] ~ lquery → boolean</code><br><code>lquery ~ ltree[] → boolean</code>       | Does array contain any path matching <code>lquery</code> ?                              |
| <code>ltree[] ? lquery[] → boolean</code><br><code>lquery[] ? ltree[] → boolean</code>   | Does <code>ltree</code> array contain any path matching any <code>lquery</code> ?       |
| <code>ltree[] @ ltxtquery → boolean</code><br><code>ltxtquery @ ltree[] → boolean</code> | Does array contain any path matching <code>ltxtquery</code> ?                           |
| <code>ltree[] ?@&gt; ltree → ltree</code>                                                | Returns first array entry that is an ancestor of <code>ltree</code> , or NULL if none.  |
| <code>ltree[] ?&lt;@ ltree → ltree</code>                                                | Returns first array entry that is a descendant of <code>ltree</code> , or NULL if none. |
| <code>ltree[] ?~ lquery → ltree</code>                                                   | Returns first array entry that matches <code>lquery</code> , or NULL if none.           |
| <code>ltree[] ?@ ltxtquery → ltree</code>                                                | Returns first array entry that matches <code>ltxtquery</code> , or NULL if none.        |

The operators `<@`, `@>`, `@` and `~` have analogues `^<@`, `^@>`, `^@`, `^~`, which are the same except they do not use indexes. These are useful only for testing purposes.

The available functions are shown in [Table F.25](#).

**Table F.25. ltree Functions**

| Function<br>Description<br>Example(s)                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>subltree ( ltree, start integer, end integer ) → ltree</code><br>Returns subpath of <code>ltree</code> from position <code>start</code> to position <code>end-1</code> (counting from 0).<br><code>subltree('Top.Child1.Child2', 1, 2) → Child1</code>                                                                                                                                                                   |
| <code>subpath ( ltree, offset integer, len integer ) → ltree</code><br>Returns subpath of <code>ltree</code> starting at position <code>offset</code> , with length <code>len</code> . If <code>offset</code> is negative, subpath starts that far from the end of the path. If <code>len</code> is negative, leaves that many labels off the end of the path.<br><code>subpath('Top.Child1.Child2', 0, 2) → Top.Child1</code> |
| <code>subpath ( ltree, offset integer ) → ltree</code><br>Returns subpath of <code>ltree</code> starting at position <code>offset</code> , extending to end of path. If <code>offset</code> is negative, subpath starts that far from the end of the path.<br><code>subpath('Top.Child1.Child2', 1) → Child1.Child2</code>                                                                                                     |
| <code>nlevel ( ltree ) → integer</code><br>Returns number of labels in path.<br><code>nlevel('Top.Child1.Child2') → 3</code>                                                                                                                                                                                                                                                                                                   |
| <code>index ( a ltree, b ltree ) → integer</code><br>Returns position of first occurrence of <code>b</code> in <code>a</code> , or -1 if not found.<br><code>index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6') → 6</code>                                                                                                                                                                                                                |
| <code>index ( a ltree, b ltree, offset integer ) → integer</code><br>Returns position of first occurrence of <code>b</code> in <code>a</code> , or -1 if not found. The search starts at position <code>offset</code> ; negative <code>offset</code> means start <code>-offset</code> labels from the end of the path.<br><code>index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6', -4) → 9</code>                                         |
| <code>text2ltree ( text ) → ltree</code><br>Casts <code>text</code> to <code>ltree</code> .                                                                                                                                                                                                                                                                                                                                    |
| <code>ltree2text ( ltree ) → text</code><br>Casts <code>ltree</code> to <code>text</code> .                                                                                                                                                                                                                                                                                                                                    |
| <code>lca ( ltree [, ltree [, ... ]] ) → ltree</code><br>Computes longest common ancestor of paths (up to 8 arguments are supported).<br><code>lca('1.2.3', '1.2.3.4.5.6') → 1.2</code>                                                                                                                                                                                                                                        |
| <code>lca ( ltree[] ) → ltree</code><br>Computes longest common ancestor of paths in array.<br><code>lca(array['1.2.3'::ltree, '1.2.3.4']) → 1.2</code>                                                                                                                                                                                                                                                                        |

### F.31.3. Indexes

`ltree` supports several types of indexes that can speed up the indicated operators:

- B-tree index over `ltree`: `<`, `<=`, `=`, `>=`, `>`
- GiST index over `ltree` (`gist_ltree_ops` opclass): `<`, `<=`, `=`, `>=`, `>`, `@>`, `<@`, `@`, `~`, `?`

`gist_ltree_ops` GiST opclass approximates a set of path labels as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 8 bytes. The length must be a positive multiple of `int` alignment (4 bytes on most machines)) up to

2024. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with the default signature length of 8 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path gist_ltree_ops(siglen=100));
```

- **GiST index over ltree[] (gist\_\_ltree\_ops opclass):** ltree[] <@ ltree, ltree @> ltree[], @, ~, ?

gist\_\_ltree\_ops GiST opclass works similarly to gist\_ltree\_ops and also takes signature length as a parameter. The default value of siglen in gist\_\_ltree\_ops is 28 bytes.

Example of creating such an index with the default signature length of 28 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path  
gist__ltree_ops(siglen=100));
```

Note: This index type is lossy.

## F.31.4. Example

This example uses the following data (also available in file contrib/ltree/ltreetest.sql in the source distribution):

```
CREATE TABLE test (path ltree);  
INSERT INTO test VALUES ('Top');  
INSERT INTO test VALUES ('Top.Science');  
INSERT INTO test VALUES ('Top.Science.Astronomy');  
INSERT INTO test VALUES ('Top.Science.Astronomy.Astrophysics');  
INSERT INTO test VALUES ('Top.Science.Astronomy.Cosmology');  
INSERT INTO test VALUES ('Top.Hobbies');  
INSERT INTO test VALUES ('Top.Hobbies.Amateurs_Astronomy');  
INSERT INTO test VALUES ('Top.Collections');  
INSERT INTO test VALUES ('Top.Collections.Pictures');  
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy');  
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Stars');  
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Galaxies');  
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Astronauts');  
CREATE INDEX path_gist_idx ON test USING GIST (path);  
CREATE INDEX path_idx ON test USING BTREE (path);
```

Now, we have a table test populated with data describing the hierarchy shown below:

```
          Top  
        /  |  \  
    Science Hobbies Collections  
      /      |      \  
 Astronomy Amateurs_Astronomy Pictures  
    /  \      |      \  
Astrophysics Cosmology      Astronomy  
                        /  |  \  
                    Galaxies Stars Astronauts
```

We can do inheritance:

```
ltreetest=> SELECT path FROM test WHERE path <@ 'Top.Science';
           path
```

```
-----
Top.Science
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(4 rows)
```

**Here are some examples of path matching:**

```
ltreetest=> SELECT path FROM test WHERE path ~ '*.Astronomy.*';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
Top.Collections.Pictures.Astronomy
Top.Collections.Pictures.Astronomy.Stars
Top.Collections.Pictures.Astronomy.Galaxies
Top.Collections.Pictures.Astronomy.Astronauts
(7 rows)
```

```
ltreetest=> SELECT path FROM test WHERE path ~ '.*!pictures@.Astronomy.*';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(3 rows)
```

**Here are some examples of full text search:**

```
ltreetest=> SELECT path FROM test WHERE path @ 'Astro*% & !pictures@';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
Top.Hobbies.Amateurs_Astronomy
(4 rows)
```

```
ltreetest=> SELECT path FROM test WHERE path @ 'Astro* & !pictures@';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(3 rows)
```

**Path construction using functions:**

```
ltreetest=> SELECT subpath(path,0,2)||'Space'||subpath(path,2) FROM test WHERE path <@
           'Top.Science.Astronomy';
           ?column?
```

```
-----
Top.Science.Space.Astronomy
Top.Science.Space.Astronomy.Astrophysics
Top.Science.Space.Astronomy.Cosmology
(3 rows)
```

We could simplify this by creating an SQL function that inserts a label at a specified position in a path:

```
CREATE FUNCTION ins_label(ltree, int, text) RETURNS ltree
AS 'select subpath($1,0,$2) || $3 || subpath($1,$2);'
LANGUAGE SQL IMMUTABLE;
```

```
ltreetest=> SELECT ins_label(path,2,'Space') FROM test WHERE path <@
            'Top.Science.Astronomy';
            ins_label
```

```
-----
Top.Science.Space.Astronomy
Top.Science.Space.Astronomy.Astrophysics
Top.Science.Space.Astronomy.Cosmology
(3 rows)
```

## F.31.5. Transforms

Additional extensions are available that implement transforms for the `ltree` type for PL/Python. The extensions are called `ltree_plpythonu`, `ltree_plpython2u`, and `ltree_plpython3u` (see [Section 48.1](#) for the PL/Python naming convention). If you install these transforms and specify them when creating a function, `ltree` values are mapped to Python lists. (The reverse is currently not supported, however.)

### Caution

It is strongly recommended that the transform extensions be installed in the same schema as `ltree`. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.

## F.31.6. Authors

All work was done by Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megera/postgres/gist/> for additional information. Authors would like to thank Eugeny Rodichev for helpful discussions. Comments and bug reports are welcome.

## F.32. mchar

The `mchar` module provides additional data types for compatibility with Microsoft SQL Server (MS SQL).

### F.32.1. Overview

This module has been designed to improve 1C Enterprise support, most popular Russian CRM and ERP system.

It implements types `MCHAR` and `MVARCHAR`, which are bug-to-bug compatible with MS SQL `CHAR` and `VARCHAR` respectively. Additionally, these types use the ICU library for comparison and case conversion, so their behavior is identical across different operating systems.

Postgres Pro also includes [citext](#) extension which provides types similar to `MCHAR`. But this extension doesn't emulate MS-SQL behavior concerning end-of-value whitespace.

Differences from Postgres Pro standard `CHAR` and `VARCHAR` are:

- Case insensitive comparison
- Handling of the whitespace at the end of string
- These types are always stored as two-byte unicode value regardless of database encoding.

### F.32.2. Additional types

- `mchar` — analog of the MS SQL char type

- `mvarchar` — analog of the MS SQL `varchar` type

For how to prevent type resolution issues associated with [pg\\_dump/pg\\_restore](#) or [pg\\_upgrade](#) for operators that use custom types, refer to [Section 10.2.1](#).

### F.32.3. MCHAR and MVARCHAR features

- Defines `length(str)` function
- Defines `substr(str, pos[, length])` function
- Defines `||` operator, which would be applied to concatenate any (`mchar` and `mvarchar`) arguments
- Defines set of operators: `<`, `<=`, `=`, `>=`, `>` for case-insensitive comparison (ICU)
- Defines set of operators: `&<`, `&<=`, `&=`, `&>=`, `&>` to case-sensitive comparison (ICU)
- Implicit cast between `mchar` and `mvarchar` types
- B-tree and Hash-index support
- The `LIKE [ESCAPE]` operator support
- The `SIMILAR TO [ESCAPE]` operator support
- The `~` operator (POSIX regexp) support
- Index support for the *LIKE* operator

### F.32.4. Authors

Oleg Bartunov <oleg@sai.msu.ru>  
Teodor Sigaev <teodor@sigaev.ru>

## F.33. multimaster

`multimaster` is a Postgres Pro Enterprise extension with a set of patches that turns Postgres Pro Enterprise into a synchronous shared-nothing cluster to provide Online Transaction Processing (OLTP) scalability for read transactions and high availability with automatic disaster recovery.

As compared to a standard PostgreSQL primary-standby cluster, a cluster configured with the `multimaster` extension offers the following benefits:

- Fault tolerance and automatic node recovery
- Synchronous logical replication and DDL replication
- Read scalability
- Working with temporary tables on each cluster node (with limitations)
- Upgrading minor releases of Postgres Pro Enterprise seamlessly for multimaster cluster clients

#### Important

Before deploying `multimaster` on production systems, make sure to take its replication restrictions into account. For details, see [Section F.33.1](#).

The `multimaster` extension replicates your database to all nodes of the cluster and allows write transactions on each node. Write transactions are synchronously replicated to all nodes, which increases commit latency. Read-only transactions and queries are executed locally, without any measurable overhead.

To ensure high availability and fault tolerance of the cluster, `multimaster` determines each transaction outcome through Paxos consensus algorithm, uses custom recovery protocol and heartbeats for failure discovery. A multi-master cluster of  $N$  nodes can continue working while the majority of the nodes are

alive and reachable by other nodes. To be configured with `multimaster`, the cluster must include at least three nodes. Since the data on all cluster nodes is the same, you do not typically need more than five cluster nodes. There is also a special 2+1 (referee) mode in which 2 nodes hold data and an additional one called *referee* only participates in voting. Compared to traditional three nodes setup, this is cheaper (referee resources demands are low) but availability is decreased. For details, see [Section F.33.3.3](#).

When a failed node is reconnected to the cluster, `multimaster` automatically fast-forwards the node to the actual state based on the Write-Ahead Log (WAL) data in the corresponding replication slot. If a node was excluded from the cluster, you can [add it back using pg\\_basebackup](#).

To learn more about the `multimaster` internals, see [Section F.33.2](#).

## F.33.1. Limitations

The `multimaster` extension takes care of the database replication in a fully automated way. You can perform write transactions on any node and work with temporary tables on each cluster node simultaneously. However, make sure to take the following replication restrictions into account:

- Microsoft Windows operating system is not supported.
- 1C solutions are not supported.
- When used with [postgres\\_fdw](#), queries to foreign tables in read-write transactions are not supported. However, you can enable support of read-only queries to foreign tables in read-write transactions by setting the value of the [postgres\\_fdw.read\\_only\\_transactions](#) configuration parameter to `on`.
- `multimaster` can replicate only one database in a cluster. If it is required to replicate the contents of several databases, you can either transfer all data into different schemas within a single database or create a separate cluster for each database and set up `multimaster` for each cluster.
- [Large objects](#) are not supported. Although creating large objects is allowed, `multimaster` cannot replicate such objects, and their OIDs may conflict on different nodes, so their use is not recommended.
- Since `multimaster` is based on [logical replication and Paxos over three-phase commit protocol](#), its operation is highly affected by network latency. It is not recommended to set up a `multimaster` cluster with geographically distributed nodes.
- Using tables without primary keys can have negative impact on performance. In some cases, it can even lead to inability to restore a cluster node, so you should avoid replicating such tables with `multimaster`.
- Unlike in vanilla PostgreSQL, `read committed` isolation level can cause serialization failures on a multi-master cluster (with an SQLSTATE code '40001') if there are conflicting transactions from different nodes, so the application must be ready to retry transactions. *Serializable* isolation level works only with respect to local transactions on the current node.
- Sequence generation. To avoid conflicts between unique identifiers on different nodes, `multimaster` modifies the default behavior of sequence generators. By default, ID generation on each node is started with this node number and is incremented by the number of nodes. For example, in a three-node cluster, 1, 4, and 7 IDs are allocated to the objects written onto the first node, while 2, 5, and 8 IDs are reserved for the second node. If you change the number of nodes in the cluster, the incrementation interval for new IDs is adjusted accordingly. Thus, the generated sequence values are not monotonic. If it is critical to get a monotonically increasing sequence cluster-wide, you can set the [multimaster.monotonic\\_sequences](#) to `true`.
- Commit latency. In the current implementation of logical replication, `multimaster` sends data to subscriber nodes only after the local commit, so you have to wait for transaction processing twice: first on the local node, and then on all the other nodes simultaneously. In the case of a heavy-write transaction, this may result in a noticeable delay.
- Logical replication does not guarantee that a system object OID is the same on all cluster nodes, so OIDs for the same object may differ between `multimaster` cluster nodes. If your driver or ap-

plication relies on OIDs, make sure that their use is restricted to connections to one and the same node to avoid errors. For example, the `Npgsql` driver may not work correctly with `multimaster` if the `NpgsqlConnection.GlobalTypeMapper` method tries using OIDs in connections to different cluster nodes.

- A `multimaster` cluster node cannot function as a logical replication subscriber. While a `multimaster` node can function as a publisher, the subscription cannot automatically switch to another node if the node fails.
- Replicated non-conflicting transactions are applied on the receiving nodes in parallel, so such transactions may become visible on different nodes in different order.
- `REINDEX CONCURRENTLY`, `CREATE TABLESPACE`, and `DROP TABLESPACE` are not replicated to other nodes.
- `CREATE INDEX CONCURRENTLY` is not supported.
- `COMMIT AND CHAIN` feature is not supported.
- `CREATE [TEMP] TABLE AS` is not supported with queries that contain explicit use of variables or arguments of functions or procedures (if the command is executed in the context of a function or procedure), and other context-sensitive objects. It is not recommended to use `CREATE TABLE AS` with the `WITH DATA` clause (data copy) in a query that uses temporary tables as it may cause the new table data synchronization issues across cluster nodes.

## F.33.2. Architecture

### F.33.2.1. Replication

Since each server in a multi-master cluster can accept writes, any server can abort a transaction because of a concurrent update — in the same way as it happens on a single server between different backends. To ensure high availability and data consistency on all cluster nodes, `multimaster` uses [logical replication](#) and the three-phase commit protocol with transaction outcome determined by [Paxos consensus algorithm](#).

When Postgres Pro Enterprise loads the `multimaster` shared library, `multimaster` sets up a logical replication producer and consumer for each node, and hooks into the transaction commit pipeline. The typical data replication workflow consists of the following phases:

1. **PREPARE phase.** `multimaster` captures and implicitly transforms each `COMMIT` statement to a `PREPARE` statement. All the nodes that get the transaction via the replication protocol (*the cohort nodes*) send their vote for approving or declining the transaction to the backend process on the initiating node. This ensures that all the cohort can accept the transaction, and no write conflicts occur. For details on `PREPARE` transactions support in PostgreSQL, see the [PREPARE TRANSACTION](#) topic.
2. **PRECOMMIT phase.** If all the cohort nodes approve the transaction, the backend process sends a `PRECOMMIT` message to all the cohort nodes to express an intention to commit the transaction. The cohort nodes respond to the backend with the `PRECOMMITTED` message. In case of a failure, all the nodes can use this information to complete the transaction using a quorum-based voting procedure.
3. **COMMIT phase.** If `PRECOMMIT` is successful, the transaction is committed to all nodes.

If a node crashes or gets disconnected from the cluster between the `PREPARE` and `COMMIT` phases, the `PRECOMMIT` phase ensures that the survived nodes have enough information to complete the prepared transaction. The `PRECOMMITTED` messages help avoid the situation when the crashed node has already committed or aborted the transaction, but has not notified other nodes about the transaction status. In a two-phase commit (2PC), such a transaction would block resources (hold locks) until the recovery of the crashed node. Otherwise, data inconsistencies can appear in the database when the failed node is recovered, for example, if the failed node committed the transaction, but the survived node aborted it.

To complete the transaction, the backend must receive a response from the majority of the nodes. For example, for a cluster of  $2N+1$  nodes, at least  $N+1$  responses are required. Thus, `multimaster` ensures

that your cluster is available for reads and writes while the majority of the nodes are connected, and no data inconsistencies occur in case of a node or connection failure.

### F.33.2.2. Failure Detection and Recovery

Since `multimaster` allows writes to each node, it has to wait for responses about transaction acknowledgment from all the other nodes. Without special actions in case of a node failure, each commit would have to wait until the failed node recovery. To deal with such situations, `multimaster` periodically sends heartbeats to check the node state and the connectivity between nodes. When several heartbeats to the node are lost in a row, this node is kicked out of the cluster to allow writes to the remaining alive nodes. You can configure the heartbeat frequency and the response timeout in the `multimaster.heartbeat_send_timeout` and `multimaster.heartbeat_recv_timeout` parameters, respectively.

For example, suppose a five-node multi-master cluster experienced a network failure that split the network into two isolated subnets, with two and three cluster nodes. Based on heartbeats propagation information, `multimaster` will continue accepting writes at each node in the bigger partition, and deny all writes in the smaller one. Thus, a cluster consisting of  $2N+1$  nodes can tolerate  $N$  node failures and stay alive if any  $N+1$  nodes are alive and connected to each other. You can also set up a two nodes cluster plus a lightweight referee node that does not hold the data, but acts as a tie-breaker during symmetric node partitioning. For details, see [Section F.33.3.3](#).

In case of a partial network split when different nodes have different connectivity, `multimaster` finds a fully connected subset of nodes and disconnects nodes outside of this subset. For example, in a three-node cluster, if node A can access both B and C, but node B cannot access node C, `multimaster` isolates node C to ensure that both A and B can work.

To preserve order of transactions on different nodes and thus data integrity, the decision to exclude or add back node(s) must be taken coherently. Generations which represent a subset of currently supposedly live nodes serve this purpose. Technically, generation is a pair `<n, members>` where  $n$  is unique number and `members` is subset of configured nodes. A node always lives in some generation and switches to the one with higher number as soon as it learns about its existence; generation numbers act as logical clocks/terms/epochs here. Each transaction is stamped during commit with current generation of the node it is being executed on. The transaction can be proposed to be committed only after it has been PREPARED on all its generation members. This allows to design the recovery protocol so that order of conflicting committed transactions is the same on all nodes. Node resides in generation in one of three states (can be shown with `mtm.status()`):

1. **ONLINE**: node is member of the generation and making transactions normally;
2. **RECOVERY**: node is member of the generation, but it must apply in recovery mode transactions from previous generations to become **ONLINE**;
3. **DEAD**: node will never be **ONLINE** in this generation;

For alive nodes, there is no way to distinguish between a failed node that stopped serving requests and a network-partitioned node that can be accessed by database users, but is unreachable for other nodes. If during commit of writing transaction some of current generation members are disconnected, transaction is rolled back according to generation rules. To avoid futile work, connectivity is also checked during transaction start; if you try to access an isolated node, `multimaster` returns an error message indicating the current status of the node. Thus, to prevent stale reads read-only queries are also forbidden. If you would like to continue using a disconnected node outside of the cluster in the standalone mode, you have to uninstall the `multimaster` extension on this node, as explained in [Section F.33.4.5](#).

Each node maintains a data structure that keeps the information about the state of all nodes in relation to this node. You can get this data by calling the `mtm.status()` and the `mtm.nodes()` functions.

When a failed node connects back to the cluster, `multimaster` starts automatic recovery:

1. The reconnected node selects a cluster node, which is **ONLINE** in the highest generation, referred to as the *donor* node, and starts catching up with the current state of the cluster based on the Write-Ahead Log (WAL).

2. When the node is caught up, it ballots for including itself in the next generation. Once generation is elected, commit of new transactions will start waiting for apply on the joining node.
3. When the rest of transactions till the switch to the new generation is applied, the reconnected node is promoted to the `online` state and included into the replication scheme.

The correctness of recovery protocol was verified with TLA+ model checker. You can find the model (and more detailed description) at [doc/specs](#) directory of the source code.

Automatic recovery requires presence of all WAL files generated after node failure. If a node is down for a long time and storing more WALs is unacceptable, you may have to exclude this node from the cluster and manually restore it from one of the working nodes using `pg_basebackup`. For details, see [Section F.33.4.3](#).

### F.33.2.3. Multimaster Background Workers

#### mtm-monitor

Starts all other workers for a database managed with multimaster. This is the first worker loaded during multimaster boot. Each multimaster node has a single `mtm-monitor` worker. When a new node is added, `mtm-monitor` starts `mtm-logrep-receiver` and `mtm-dmq-receiver` workers to enable replication to this node. If a node is dropped, `mtm-monitor` stops `mtm-logrep-receiver` and `mtm-dmq-receiver` workers that have been serving the dropped node. Each `mtm-monitor` controls workers on its own node only.

#### mtm-logrep-receiver

Receives logical replication stream from a given peer node. During normal operation, `mtm-logrep-receiver` sends replicated transactions to the pool of dynamic workers (see [mtm-logrep-receiver-dynworker](#)). During catchup, depending on the value of the [multimaster.catchup\\_algorithm](#) configuration parameter, `mtm-logrep-receiver` applies replicated transactions on the reconnected node or sends them to the pool of dynamic workers. The number of `mtm-logrep-receiver` workers on each node corresponds to the number of peer nodes available.

#### mtm-dmq-receiver

Receives acknowledgment for transactions sent to peers and checks for heartbeat timeouts. The number of `mtm-logrep-receiver` workers on each node corresponds to the number of peer nodes available.

#### mtm-dmq-sender

Collects acknowledgment for transactions applied on the current node and sends them to the corresponding [mtm-dmq-receiver](#) on the peer node. There is a single worker per Postgres Pro Enterprise instance.

#### mtm-logrep-receiver-dynworker

Dynamic pool worker for a given [mtm-logrep-receiver](#). Applies replicated transactions received during normal operation or catchup. You can use the [multimaster.max\\_workers](#) configuration parameter to specify the maximum number of dynamic workers.

#### mtm-resolver

Performs Paxos to resolve unfinished transactions. This worker is only active during recovery or when connection with other nodes was lost. There is a single worker per Postgres Pro Enterprise instance.

#### mtm-campaigner

Ballots for new generations to exclude some node(s) or add myself. There is a single worker per Postgres Pro Enterprise instance.

#### mtm-replier

Responds to requests of [mtm-campaigner](#) and [mtm-resolver](#).

## F.33.3. Installation and Setup

To use `multimaster`, you need to install Postgres Pro Enterprise on all nodes of your cluster. Postgres Pro Enterprise includes all the required dependencies and extensions.

### F.33.3.1. Setting up a Multi-Master Cluster

Suppose you are setting up a cluster of three nodes, with `node1`, `node2`, and `node3` host names. After installing Postgres Pro Enterprise on all nodes, you need to initialize data directory on each node, as explained in [Section 18.2](#). If you would like to set up a multi-master cluster for an already existing `mydb` database, you can load data from `mydb` to one of the nodes once the cluster is initialized, or you can load data to all new nodes before cluster initialization using any convenient mechanism, such as `pg_basebackup` or `pg_dump`.

Once the data directory is set up, complete the following steps on each cluster node:

1. Modify the `postgresql.conf` configuration file, as follows:

- Add `multimaster` to the `shared_preload_libraries` variable:

```
shared_preload_libraries = 'multimaster'
```

#### Tip

If the `shared_preload_libraries` variable is already defined in `postgresql.auto.conf`, you will need to modify its value using the `ALTER SYSTEM` command. For details, see [Section 19.1.2](#). Note that in a multi-master cluster, the `ALTER SYSTEM` command only affects the configuration of the node from which it was run.

- Set up Postgres Pro Enterprise parameters related to replication:

```
wal_level = logical
max_connections = 100
max_prepared_transactions = 300 # max_connections * N
max_wal_senders = 10           # at least N
max_replication_slots = 10     # at least 2N
wal_sender_timeout = 0
```

where  $N$  is the number of nodes in your cluster.

You must change the replication level to `logical` as `multimaster` relies on logical replication. For a cluster of  $N$  nodes, enable at least  $N$  WAL sender processes and replication slots. Since `multimaster` implicitly adds a `PREPARE` phase to each `COMMIT` transaction, make sure to set the number of prepared transactions to  $N * \text{max\_connections}$ . `wal_sender_timeout` should be disabled as `multimaster` uses its custom logic for failure detection.

- Make sure you have enough background workers allocated for each node:

```
max_worker_processes = 250 # (N - 1) * (multimaster.max_workers + 1) + 5
```

For example, for a three-node cluster with `multimaster.max_workers = 100`, `multimaster` may need up to 207 background workers at peak times: five always-on workers (monitor, resolver, dmq-sender, campaigner, replier), one walreceiver per each peer node and up to 200 replication dynamic workers. When setting this parameter, remember that other modules may also use background workers at the same time.

- Depending on your network environment and usage patterns, you may want to tune other `multimaster` parameters. For details, see [Section F.33.3.2](#).

2. Start Postgres Pro Enterprise on all nodes.

3. Create database `mydb` and user `mtmuser` on each node:

```
CREATE USER mtmuser WITH SUPERUSER PASSWORD 'mtmuserpassword';
CREATE DATABASE mydb OWNER mtmuser;
```

If you are using password-based authentication, you may want to create a [password file](#).

You can omit this step if you already have a database you are going to replicate, but you are recommended to create a separate superuser for multi-master replication. The examples below assume that you are going to replicate the `mydb` database on behalf of `mtmuser`.

4. Allow replication of the `mydb` database to each cluster node on behalf of `mtmuser`, as explained in [Section 20.1](#). Make sure to use the [authentication method](#) that satisfies your security requirements. For example, `pg_hba.conf` might have the following lines on `node1`:

```
host replication mtmuser node2 md5
host mydb mtmuser node2 md5
host replication mtmuser node3 md5
host mydb mtmuser node3 md5
```

5. Connect to any node on behalf of the `mtmuser` database user, create the `multimaster` extension in the `mydb` database and run `mtm.init_cluster()`, specifying the connection string to the current node as the first argument and an array of connection strings to the other nodes as the second argument.

For example, if you would like to connect to `node1`, run:

```
CREATE EXTENSION multimaster;
SELECT mtm.init_cluster('dbname=mydb user=mtmuser host=node1',
  '{"dbname=mydb user=mtmuser host=node2", "dbname=mydb user=mtmuser host=node3"}');
```

6. To ensure that `multimaster` is enabled, you can run the `mtm.status()` and `mtm.nodes()` functions:

```
SELECT * FROM mtm.status();
SELECT * FROM mtm.nodes();
```

If `status` is equal to `online` and all nodes are present in the `mtm.nodes` output, your cluster is successfully configured and ready to use.

### Tip

If you have any data that must be present on one of the nodes only, you can exclude a particular table from replication, as follows:

```
SELECT mtm.make_table_local('table_name')
```

## F.33.3.2. Tuning Configuration Parameters

While you can use `multimaster` in the default configuration, you may want to tune several parameters for faster failure detection or more reliable automatic recovery.

### F.33.3.2.1. Setting Timeout for Failure Detection

To check availability of the peer nodes, `multimaster` periodically sends heartbeat packets to all nodes. You can define the timeout for failure detection with the following variables:

- The `multimaster.heartbeat_send_timeout` variable defines the time interval between the heartbeats. By default, this variable is set to 200ms.
- The `multimaster.heartbeat_rcv_timeout` variable sets the timeout for the response. If no heartbeats are received during this time, the node is assumed to be disconnected and is excluded from the cluster. By default, this variable is set to 2000ms.

It's a good idea to set `multimaster.heartbeat_send_timeout` based on typical ping latencies between the nodes. Small `rcv/send` ratio decreases the time of failure detection, but increases the probability of

false-positive failure detection. When setting this parameter, take into account the typical packet loss ratio between your cluster nodes.

### F.33.3.3. 2+1 Mode: Setting up a Standalone Referee Node

By default, `multimaster` uses a majority-based algorithm to determine whether the cluster nodes have a quorum: a cluster can only continue working if the majority of its nodes are alive and can access each other. Majority-based approach is pointless for two nodes cluster: if one of them fails, another one becomes inaccessible. There is a special 2+1 or referee mode which trades less hardware resources by decreasing availability: two nodes hold full copy of data, and separate referee node participates only in voting, acting as a tie-breaker.

If one node goes down, another one requests referee grant (elects referee-approved generation with single node). Once the grant is received, it continues to work normally. If offline node gets up, it recovers and elects full generation containing both nodes, essentially removing the grant - this allows the node to get it in its turn later. While the grant is issued, it can't be given to another node until full generation is elected and excluded node recovers. This ensures data loss doesn't happen by the price of availability: in this setup two nodes (one normal and one referee) can be alive but cluster might be still unavailable if the referee winner is down, which is impossible with classic three nodes configuration.

The referee node does not store any cluster data, so it is not resource-intensive and can be configured on virtually any system with Postgres Pro Enterprise installed.

To avoid split-brain problems, you must have only a single referee in your cluster.

To set up a referee for your cluster:

1. Install Postgres Pro Enterprise on the node you are going to make a referee and create the `referee` extension:

```
CREATE EXTENSION referee;
```

2. Make sure the `pg_hba.conf` file allows access to the referee node.
3. Set up the nodes that will hold cluster data following the instructions in [Section F.33.3.1](#).
4. On all data nodes, specify the referee connection string in the `postgresql.conf` file:

```
multimaster.referee_connstring = connstring
```

where *connstring* holds [libpq options](#) required to access the referee.

The first subset of nodes that gets connected to the referee wins the voting and starts working. The other nodes have to go through the recovery process to catch up with them and join the cluster. Under heavy load, the recovery can take unpredictably long, so it is recommended to wait for all data nodes going online before switching on the load when setting up a new cluster. Once all the nodes get online, the referee discards the voting result, and all data nodes start operating together.

In case of any failure, the voting mechanism is triggered again. At this time, all nodes appear to be offline for a short period of time to allow the referee to choose a new winner, so you can see the following error message when trying to access the cluster: `[multimaster] node is not online: current status is "disabled"`.

## F.33.4. Multi-Master Cluster Administration

- [Monitoring the Cluster Status](#)
- [Accessing Disabled Nodes](#)
- [Adding New Nodes to the Cluster](#)
- [Removing Nodes from the Cluster](#)
- [Checking Data Consistency Across Cluster Nodes](#)

- [Delayed Transaction Commits](#)

### F.33.4.1. Monitoring Cluster Status

`multimaster` provides several functions to check the current cluster state.

To check node-specific information, use `mtm.status()`:

```
SELECT * FROM mtm.status();
```

To get the list of all nodes in the cluster together with their status, use `mtm.nodes()`:

```
SELECT * FROM mtm.nodes();
```

For details on all the returned information, see [Section F.33.5.2](#).

### F.33.4.2. Accessing Disabled Nodes

If a cluster node is disabled, any attempt to read or write data on this node raises an error by default. If you need to access the data on a disabled node, you can override this behavior at connection time by setting the [application\\_name](#) parameter to `mtm_admin`. In this case, you can run read and write queries on this node without `multimaster` supervision.

### F.33.4.3. Adding New Nodes to the Cluster

#### Note

You must add nodes one by one. Avoid adding several nodes in parallel as this could cause errors.

With the `multimaster` extension, you can add or drop cluster nodes. Before adding node, stop the load and ensure (with `mtm.status()`) that all nodes are online. When adding a new node, you need to load all the data to this node using `pg_basebackup` from any cluster node, and then start this node.

Suppose we have a working cluster of three nodes, with `node1`, `node2`, and `node3` host names. To add `node4`, follow these steps:

1. Figure out the required connection string to access the new node. For example, for the database `mydb`, user `mtmuser`, and the new node `node4`, the connection string can be `"dbname=mydb user=mtmuser host=node4"`.

2. In `psql` connected to any alive node, run:

```
SELECT mtm.add_node('dbname=mydb user=mtmuser host=node4');
```

This command changes the cluster configuration on all nodes and creates replication slots for the new node. It also returns `node_id` of the new node, which will be required to complete the setup.

3. Go to the new node and clone all the data from one of the alive nodes to this node:

```
pg_basebackup -D datadir -h node1 -U mtmuser -c fast -v
```

`pg_basebackup` copies the entire data directory from `node1`, together with configuration settings, and prints the last LSN replayed from WAL, such as `'0/12D357F0'`. This value will be required to complete the setup.

4. Configure the new node to boot with `recovery_target=immediate` to prevent redo past the point where replication will begin. Add to `postgresql.conf`:

```
restore_command = 'false'
recovery_target = 'immediate'
recovery_target_action = 'promote'
```

And create `recovery.signal` file in the data directory.

5. Start Postgres Pro Enterprise on the new node.
6. In `psql` connected to the node used to take the base backup, run:

```
SELECT mtm.join_node(4, '0/12D357F0');
```

where 4 is the `node_id` returned by the `mtm.add_node()` function call and '0/12D357F0' is the LSN value returned by `pg_basebackup`.

#### F.33.4.4. Removing Nodes from the Cluster

Before removing node, stop the load and ensure (with `mtm.status()`) that all nodes (except the ones to be dropped) are online. Shut down the nodes you are going to remove. To remove the node from the cluster:

1. Run the `mtm.nodes()` function to learn the ID of the node to be removed:

```
SELECT * FROM mtm.nodes();
```

2. Run the `mtm.drop_node()` function with this node ID as a parameter:

```
SELECT mtm.drop_node(3);
```

This will delete replication slots for node 3 on all cluster nodes and stop replication to this node.

If you would like to return the node to the cluster later, you will have to add it as a new node, as explained in [Section F.33.4.3](#).

#### F.33.4.5. Uninstalling the multimaster Extension

If you would like to continue using the node that has been removed from the cluster in the standalone mode, you have to drop the `multimaster` extension on this node and clean up all `multimaster`-related subscriptions and uncommitted transactions to ensure that the node is no longer associated with the cluster.

1. Remove `multimaster` from [shared\\_preload\\_libraries](#) and restart Postgres Pro Enterprise.
2. Delete the `multimaster` extension and publication:

```
DROP EXTENSION multimaster;  
DROP PUBLICATION multimaster;
```

3. Review the list of existing subscriptions using the `\dRs` command and delete each subscription that starts with the `mtm_sub_` prefix:

```
\dRs  
DROP SUBSCRIPTION mtm_sub_subscription_name;
```

4. Review the list of existing replication slots and delete each slot that starts with the `mtm_` prefix:

```
SELECT * FROM pg_replication_slots;  
SELECT pg_drop_replication_slot('mtm_slot_name');
```

5. Review the list of existing replication origins and delete each origin that starts with the `mtm_` prefix:

```
SELECT * FROM pg_replication_origin;  
SELECT pg_replication_origin_drop('mtm_origin_name');
```

6. Review the list of prepared transaction left, if any:

```
SELECT * FROM pg_prepared_xacts;
```

You have to commit or abort these transactions by running `ABORT PREPARED transaction_id` or `COMMIT PREPARED transaction_id`, respectively.

Once all these steps are complete, you can start using the node in the standalone mode, if required.

### F.33.4.6. Checking Data Consistency Across Cluster Nodes

You can check that the data is the same on all cluster nodes using the `mtm.check_query(query_text)` function.

As a parameter, this function takes the text of a query you would like to run for data comparison. When you call this function, it takes a consistent snapshot of data on each cluster node and runs this query against the captured snapshots. The query results are compared between pairs of nodes. If there are no differences, this function returns `true`. Otherwise, it reports the first detected difference in a warning and returns `false`.

To avoid false-positive results, always use the `ORDER BY` clause in your test query. For example, suppose you would like to check that the data in a `my_table` is the same on all cluster nodes. Compare the results of the following queries:

```
postgres=# SELECT mtm.check_query('SELECT * FROM my_table ORDER BY id');
check_query
-----
t
(1 row)

postgres=# SELECT mtm.check_query('SELECT * FROM my_table');
WARNING: mismatch in column 'b' of row 0: 256 on node0, 255 on node1
check_query
-----
f
(1 row)
```

Even though the data is the same, the second query reports an issue because the order of the returned data differs between cluster nodes.

### F.33.4.7. Delayed Transaction Commits

When a lagging node is catching up to the donor node and cannot apply changes as quickly, you can slow down transaction execution on the donor node using the `multimaster.tx_delay_on_slow_catchup` configuration parameter. To do this, set this parameter to `on` in the `postgresql.conf` configuration file on the donor node, but not on the lagging peer node. If you edit the file on a running server, you will need to signal the postmaster to make it re-read the file (see [Chapter 19](#) for details). If necessary, you can also specify the maximum possible delay for transaction execution in the optional `multimaster.max_tx_delay_on_slow_catchup` parameter (in milliseconds). A value of 0 means that no maximum delay is set. Currently, delays can range from 1 ms to approximately 4 seconds. Values outside the allowed range will be truncated towards the nearest valid value.

By default, this feature is disabled.

## F.33.5. Reference

### F.33.5.1. Configuration Parameters

`multimaster.heartbeat_recv_timeout`

Timeout, in milliseconds. If no heartbeat message is received from the node within this timeframe, the node is excluded from the cluster.

Default: 2000 ms

`multimaster.heartbeat_send_timeout`

Time interval between heartbeat messages, in milliseconds. An arbiter process broadcasts heartbeat messages to all nodes to detect connection problems.

Default: 200 ms

`multimaster.max_workers`

The maximum number of `walreceiver` workers per peer node.

### Important

This parameter should be used with caution. If the number of simultaneous transactions in the whole cluster is bigger than the provided value, it can lead to undetected deadlocks.

Default: 100

`multimaster.monotonic_sequences`

Defines the sequence generation mode for unique identifiers. This variable can take the following values:

- `false` (default) — ID generation on each node is started with this node number and is incremented by the number of nodes. For example, in a three-node cluster, 1, 4, and 7 IDs are allocated to the objects written onto the first node, while 2, 5, and 8 IDs are reserved for the second node. If you change the number of nodes in the cluster, the incrementation interval for new IDs is adjusted accordingly.
- `true` — the generated sequence increases monotonically cluster-wide. ID generation on each node is started with this node number and is incremented by the number of nodes, but the values are omitted if they are smaller than the already generated IDs on another node. For example, in a three-node cluster, if 1, 4 and 7 IDs are already allocated to the objects on the first node, 2 and 5 IDs will be omitted on the second node. In this case, the first ID on the second node is 8. Thus, the next generated ID is always higher than the previous one, regardless of the cluster node.

Default: `false`

`multimaster.referee_connstring`

Connection string to access the referee node. You must set this parameter on all cluster nodes if the referee is set up.

`multimaster.remote_functions`

Provides a comma-separated list of function names that should be executed remotely on all multimaster nodes instead of replicating the result of their work.

`multimaster.trans_spill_threshold`

The maximal size of transaction, in kB. When this threshold is reached, the transaction is written to the disk.

Default: 100MB

`multimaster.break_connection`

Break connection with clients connected to the node if this node disconnects from the cluster. If this variable is set to `false`, the client stays connected to the node but receives an error that the node is disabled.

Default: `false`

`multimaster.connect_timeout`

Maximum time to wait while connecting, in seconds. Zero, negative, or not specified means wait indefinitely. The minimum allowed timeout is 2 seconds, therefore a value of 1 is interpreted as 2.

Default: 0

`multimaster.ignore_tables_without_pk`

Do not replicate tables without primary key. When `false`, such tables are replicated.

Default: `false`

`multimaster.syncpoint_interval`

Amount of WAL generated between synchronization points.

Default: 10 MB

`multimaster.binary_basetypes`

Send data of built-in types in binary format.

Default: `true`

`multimaster.wait_peer_commits`

Wait until all peers commit the transaction before the command returns a success indication to the client.

Default: `true`

`multimaster.deadlock_prevention`

Manage prevention of transaction deadlocks that can occur when the same tuple is updated or deleted on different nodes simultaneously. If set to `off`, deadlock prevention is disabled.

If set to `simple`, the conflicting transactions are rejected. This setting may be used in any setup.

If set to `smart`, a specific algorithm is used to provide best resource availability by selectively committing or rejecting transactions. This is recommended for a setup of [two nodes and a referee](#). In three node setups, deadlocks are still possible. If there are more than four nodes, all conflicting transactions are rejected, just as with `simple`.

Default: `off`

`multimaster.tx_delay_on_slow_catchup`

Enable delay of transaction commits on the donor node when peer nodes are catching up to this node. This parameter should only be set on the donor node.

Default: `off`

`multimaster.max_tx_delay_on_slow_catchup`

If [multimaster.tx\\_delay\\_on\\_slow\\_catchup](#) is enabled, this parameter specifies maximum transaction execution delay, in milliseconds. Possible values are integers greater than 0, but it allows values only up to 4 seconds.

Default: 0

`multimaster.enable_async_3pc_on_catchup`

Enables asynchronous commit operations (`PREPARE`, `PRECOMMIT`, and `COMMIT PREPARED`) on a lagging node syncing with the donor node. This significantly accelerates the catchup process. Data integrity is maintained using the synchronization point mechanism: during catchup, the system periodically creates synchronization points when all preceding transactions are safely written to disk. This way, even if the lagging node is restarted, no transaction data is lost.

Default: `true`

`multimaster.catchup_algorithm`

Catchup mode for reconnected nodes. It determines how replicated transactions are applied on the reconnected node that is catching up. This configuration parameter can take one of the following values:

- `sequential` — `mtm-logrep-receiver` applies replicated transactions sequentially in the order they are received.
- `parallel` — `mtm-logrep-receiver` sends replicated transactions to the pool of dynamic workers (see [mtm-logrep-receiver-dynworker](#)). Dynamic workers apply non-conflicting transactions in parallel and conflicting transactions sequentially in the receiving order, similar to the `sequential` catchup mode. You can use the [multimaster.parallel\\_catchup\\_workers](#) configuration parameter to specify the maximum number of dynamic workers that can apply replicated transactions in this catchup mode.

Default: `sequential`

`multimaster.parallel_catchup_workers`

The maximum number of dynamic workers that can apply replicated transactions on the reconnected node in the `parallel` catchup mode. The value of this configuration parameter cannot be greater than that of the [multimaster.max\\_workers](#) configuration parameter. You can use the [multimaster.catchup\\_algorithm](#) configuration parameter to specify the catchup mode for reconnected nodes.

Default: 8

### F.33.5.2. Functions

`mtm.init_cluster(my_conninfo text, peers_conninfo text[])`

Initializes cluster configuration on all nodes. It connects the current node to all nodes listed in `peers_conninfo` and creates the multimaster extension, replications slots, and replication origins on each node. Run this function once all the nodes are running and can accept connections.

Arguments:

- `my_conninfo` — connection string to the node on which you are running this function. Peer nodes use this string to connect back to this node.
- `peers_conninfo` — an array of connection strings to all the other nodes to be added to the cluster.

`mtm.add_node(connstr text)`

Adds a new node to the cluster. This function should be called before loading data to this node using `pg_basebackup`. `mtm.add_node` creates the required replication slots for a new node, so you can add a node while the cluster is under load.

Arguments:

- `connstr` — connection string for the new node. For example, for the database `mydb`, user `mtmuser`, and the new node `node4`, the connection string is `"dbname=mydb user=mtmuser host=node4"`.

`mtm.join_node(node_id int, backup_end_lsn pg_lsn)`

Completes the cluster setup after adding a new node. This function should be called after the added node has been started.

Arguments:

- *node\_id* — ID of the node to add to the cluster. It corresponds to the value in the *id* column returned by `mtm.nodes()`.

*backup\_end\_lsn* — the last LSN of the base backup copied to the new node. This LSN will be used as the starting point for data replication once the node joins the cluster.

`mtm.drop_node(node_id integer)`

Excludes a node from the cluster.

If you would like to continue using this node outside of the cluster in the standalone mode, you have to uninstall the `multimaster` extension from this node, as explained in [Section F.33.4.5](#).

Arguments:

- *node\_id* — ID of the node being dropped. It corresponds to the value in the *id* column returned by `mtm.nodes()`.

`mtm.alter_sequences()`

Fixes unique identifiers on all cluster nodes. This may be required after restoring all nodes from a single base backup.

`mtm.status()`

Shows the status of the `multimaster` extension on the current node. Returns a tuple of the following values:

- *my\_node\_id*, *int* — ID of this node.
- *status*, *text* — status of the node. Possible values are: `online`, `recovery`, `catchup`, `disabled` (need to recover, but not yet clear from whom), `isolated` (online in current generation, but some members are disconnected).
- *connected*, *int[]* — array of peer IDs connected to this node.
- *gen\_num*, *int8* — current generation number.
- *gen\_members*, *int[]* — array of current generation members node IDs.
- *gen\_members\_online*, *int[]* — array of current generation members node IDs which are online in it.
- *gen\_configured*, *int[]* — array of node IDs configured in current generation.

`mtm.nodes()`

Shows the information on all nodes in the cluster. Returns a tuple of the following values:

- *id*, *integer* — node ID.
- *conninfo*, *text* — connection string to this node.
- *is\_self*, *boolean* — is it me?
- *enabled*, *boolean* — is this node online in current generation?
- *connected*, *boolean* — shows whether the node is connected to our node.
- *sender\_pid*, *integer* — WAL sender process ID.
- *receiver\_pid*, *integer* — WAL receiver process ID.
- *n\_workers*, *text* — number of started dynamic apply workers from this node.
- *receiver\_mode*, *text* — in which mode receiver from this node works. Possible values are: `disabled`, `recovery`, `normal`.

`mtm.make_table_local(relation regclass)`

Stops replication for the specified table.

Arguments:

- *relation* — the table you would like to exclude from the replication scheme.

`mtm.check_query(query_text text)`

Checks data consistency across cluster nodes. This function takes a snapshot of the current state of each node, runs the specified query against these snapshots, and compares the results. If the results are different between any two nodes, displays a warning with the first found issue and returns `false`. Otherwise, returns `true`.

Arguments:

- *query\_text* — the query you would like to run on all nodes for data comparison. To avoid false-positive results, always use the `ORDER BY` clause in the test query.

`mtm.get_snapshots()`

Takes a snapshot of data on each cluster node and returns the snapshot ID. The snapshots remain available until the `mtm.free_snapshots()` is called, or the current session is terminated. This function is used by the [mtm.check\\_query\(query\\_text\)](#), there is no need to call it manually.

`mtm.free_snapshots()`

Removes data snapshots taken by the `mtm.get_snapshots()` function. This function is used by the [mtm.check\\_query\(query\\_text\)](#), there is no need to call it manually.

## F.33.6. Compatibility

### F.33.6.1. Local and Global DDL Statements

By default, any DDL statement is executed on all cluster nodes, except the following statements that can only act locally on a given node:

- `ALTER SYSTEM`
- `CREATE DATABASE`
- `DROP DATABASE`
- `REINDEX`
- `CHECKPOINT`
- `CLUSTER`
- `LOAD`
- `LISTEN`
- `CHECKPOINT`
- `NOTIFY`

## F.33.7. Authors

Postgres Professional, Moscow, Russia.

### F.33.7.1. Credits

The replication mechanism is based on logical decoding and an earlier version of the `pglogical` extension provided for community by the 2ndQuadrant team.

The Paxos consensus algorithm is described at:

- Leslie Lamport. [The Part-Time Parliament](#)

Parallel replication and recovery mechanism is similar to the one described in:

- Odorico M. Mendizabal, et al. [Checkpointing in Parallel State-Machine Replication](#).

## F.34. online\_analyze

The `online_analyze` module provides a set of features that immediately update statistics after `INSERT`, `UPDATE`, `DELETE`, `SELECT INTO`, or `COPY` operations for the affected tables.

### Note

This extension cannot be used together with autonomous transactions or while built-in connection pooling is enabled.

### Note

It is not recommended to use this module with modern versions of 1C.

However, you can enable `online_analyze` if background updates do not provide the desired result or if the optimizer frequently fails to estimate the row count.

The instruction below is relevant only if you decide to use the module.

### F.34.1. Module Loading

To use `online_analyze` module, load the shared library:

```
LOAD 'online_analyze';
```

### F.34.2. Module Configuration

You can configure `online_analyze` using the following custom variables (default values are shown):

- `online_analyze.enable = on`

Enables `online_analyze`.

- `online_analyze.verbose = on`

Executes `ANALYZE VERBOSE`.

### Note

Since `verbose` is a reserved SQL key word, this parameter has to be double-quoted when used in SQL queries. For example:

```
ALTER SYSTEM SET "online_analyze.verbose" = 'off';
```

- `online_analyze.scale_factor = 0.1`

Fraction of table size to start online analysis (similar to [autovacuum\\_analyze\\_scale\\_factor](#)).

- `online_analyze.threshold = 50`

Minimum number of row updates before starting online analysis (similar to [autovacuum\\_analyze\\_threshold](#)).

- `online_analyze.min_interval = 10000`

Minimum time interval between `ANALYZE` calls per table, in milliseconds.

- `online_analyze.table_type = "all"`

Type(s) of tables for online analysis. Possible values are: `all`, `persistent`, `temporary`, `none`.

- `online_analyze.exclude_tables = ""`

List of tables to exclude from online analysis.

- `online_analyze.include_tables = ""`

List of tables to include in online analysis (`online_analyze.include_tables` overrides `online_analyze.exclude_tables`).

- `online_analyze.local_tracking = off`

Enables per-backend tracking for temporary tables by `online_analyze`. When this variable is set to `off`, `online_analyze` uses the default system statistics for temporary tables.

- `online_analyze.lower_limit = 0`

Minimum number of rows in a table required to trigger `online_analyze`.

- `online_analyze.capacity_threshold = 100000`

Maximum number of temporary tables to store in local cache.

### F.34.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

## F.35. old\_snapshot

The `old_snapshot` module allows inspection of the server state that is used to implement [old\\_snapshot\\_threshold](#).

### F.35.1. Functions

`pg_old_snapshot_time_mapping(array_offset OUT int4, end_timestamp OUT timestamptz, newest_xmin OUT xid) returns setof record`

Returns all of the entries in the server's timestamp to XID mapping. Each entry represents the newest xmin of any snapshot taken in the corresponding minute.

## F.36. pageinspect

The `pageinspect` module provides functions that allow you to inspect the contents of database pages at a low level, which is useful for debugging purposes. All of these functions may be used only by superusers.

### F.36.1. General Functions

`get_raw_page(relname text, fork text, blkno bigint) returns bytea`

`get_raw_page` reads the specified block of the named relation and returns a copy as a `bytea` value. This allows a single time-consistent copy of the block to be obtained. `fork` should be `'main'` for

---

the main data fork, 'fsm' for the free space map, 'vm' for the visibility map, or 'init' for the initialization fork.

`get_raw_page(relname text, blkno bigint)` returns `bytea`

A shorthand version of `get_raw_page`, for reading from the main fork. Equivalent to `get_raw_page(relname, 'main', blkno)`

`page_header(page bytea)` returns `record`

`page_header` shows fields that are common to all Postgres Pro heap and index pages.

A page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM page_header(get_raw_page('pg_class', 0));
   lsn      | checksum | flags | lower | upper | special | pagesize | version |
   xid_base | multi_base | prune_xid
-----+-----+-----+-----+-----+-----+-----+-----
0/1605260 |      6885 |      1 |    204 |   7480 |      8168 |      8192 |      254 |
0 |          |      0 |          |          |          |          |          |
```

The returned columns correspond to the fields in the `PageHeaderData` struct.

The `checksum` field is the checksum stored in the page, which might be incorrect if the page is somehow corrupted. If data checksums are not enabled for this instance, then the value stored is meaningless.

`page_checksum(page bytea, blkno bigint)` returns `smallint`

`page_checksum` computes the checksum for the page, as if it was located at the given block.

A page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT page_checksum(get_raw_page('pg_class', 0), 0);
 page_checksum
-----
          13443
```

Note that the checksum depends on the block number, so matching block numbers should be passed (except when doing esoteric debugging).

The checksum computed with this function can be compared with the `checksum` result field of the function `page_header`. If data checksums are enabled for this instance, then the two values should be equal.

`fsm_page_contents(page bytea)` returns `text`

`fsm_page_contents` shows the internal node structure of an FSM page. For example:

```
test=# SELECT fsm_page_contents(get_raw_page('pg_class', 'fsm', 0));
```

The output is a multiline string, with one line per node in the binary tree within the page. Only those nodes that are not zero are printed. The so-called "next" pointer, which points to the next slot to be returned from the page, is also printed.

## F.36.2. Heap Functions

`heap_page_items(page bytea)` returns `setof record`

`heap_page_items` shows all line pointers on a heap page. For those line pointers that are in use, tuple headers as well as tuple raw data are also shown. All tuples are shown, whether or not the tuples were visible to an MVCC snapshot at the time the raw page was copied.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_items(get_raw_page('pg_class', 0));
```

The `heap_tuple_infomask_flags` function can be used to unpack the flag bits of `t_infomask` and `t_infomask2` for heap tuples.

`tuple_data_split(rel_oid oid, t_data bytea, t_infomask integer, t_infomask2 integer, t_bits text [, do_detoast bool])` returns `bytea[]`

`tuple_data_split` splits tuple data into attributes in the same way as backend internals.

```
test=# SELECT tuple_data_split('pg_class'::regclass, t_data, t_infomask,
    t_infomask2, t_bits) FROM heap_page_items(get_raw_page('pg_class', 0));
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

If `do_detoast` is true, attributes will be detoasted as needed. Default value is false.

`heap_page_item_attrs(page bytea, rel_oid regclass [, do_detoast bool])` returns set of record

`heap_page_item_attrs` is equivalent to `heap_page_items` except that it returns tuple raw data as an array of attributes that can optionally be detoasted by `do_detoast` which is false by default.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_item_attrs(get_raw_page('pg_class', 0),
    'pg_class'::regclass);
```

`heap_tuple_infomask_flags(t_infomask integer, t_infomask2 integer)` returns record

`heap_tuple_infomask_flags` decodes the `t_infomask` and `t_infomask2` returned by `heap_page_items` into a human-readable set of arrays made of flag names, with one column for all the flags and one column for combined flags. For example:

```
test=# SELECT t_ctid, raw_flags, combined_flags
    FROM heap_page_items(get_raw_page('pg_class', 0)),
    LATERAL heap_tuple_infomask_flags(t_infomask, t_infomask2)
    WHERE t_infomask IS NOT NULL OR t_infomask2 IS NOT NULL;
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

Combined flags are displayed for source-level macros that take into account the value of more than one raw bit, such as `HEAP_XMIN_FROZEN`.

### F.36.3. B-Tree Functions

`bt_metap(relname text)` returns record

`bt_metap` returns information about a B-tree index's metapage. For example:

```
test=# SELECT * FROM bt_metap('pg_cast_oid_index');
-[ RECORD 1 ]-----+-----
magic          | 340322
version        | 4
root           | 1
level          | 0
fastroot       | 1
fastlevel      | 0
last_cleanup_num_delpages | 0
last_cleanup_num_tuples  | 230
allequalimage  | f
```

Additional Supplied Modules  
and Extensions Shipped in  
postgrespro-ent-14-contrib

bt\_page\_stats(relname text, blkno bigint) returns record

bt\_page\_stats returns summary information about single pages of B-tree indexes. For example:

```
test=# SELECT * FROM bt_page_stats('pg_cast_oid_index', 1);
-[ RECORD 1 ]-----
blkno          | 1
type           | 1
live_items     | 224
dead_items     | 0
avg_item_size  | 16
page_size      | 8192
free_size      | 3668
btpo_prev      | 0
btpo_next      | 0
btpo_level     | 0
btpo_flags     | 3
```

bt\_page\_items(relname text, blkno bigint) returns setof record

bt\_page\_items returns detailed information about all of the items on a B-tree index page. For example:

```
test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data, dead, htid, tids[0:2] AS
some_tids
FROM bt_page_items('tenk2_hundred', 5);
 itemoffset |   ctid   | itemlen | nulls | vars |          data          | dead | htid |
+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+
1 | (16,1) | 16 | f | f | 30 00 00 00 00 00 00 00 |  |

(13 rows)
```

This is a B-tree leaf page. All tuples that point to the table happen to be posting list tuples (all of which store a total of 100 6 byte TIDs). There is also a “high key” tuple at itemoffset number 1. ctid

is used to store encoded information about each tuple in this example, though leaf page tuples often store a heap TID directly in the `ctid` field instead. `tids` is the list of TIDs stored as a posting list.

In an internal page (not shown), the block number part of `ctid` is a “downlink”, which is a block number of another page in the index itself. The offset part (the second number) of `ctid` stores encoded information about the tuple, such as the number of columns present (suffix truncation may have removed unneeded suffix columns). Truncated columns are treated as having the value “minus infinity”.

`htid` shows a heap TID for the tuple, regardless of the underlying tuple representation. This value may match `ctid`, or may be decoded from the alternative representations used by posting list tuples and tuples from internal pages. Tuples in internal pages usually have the implementation level heap TID column truncated away, which is represented as a NULL `htid` value.

Note that the first item on any non-rightmost page (any page with a non-zero value in the `btpo_next` field) is the page’s “high key”, meaning its `data` serves as an upper bound on all items appearing on the page, while its `ctid` field does not point to another block. Also, on internal pages, the first real data item (the first item that is not a high key) reliably has every column truncated away, leaving no actual value in its `data` field. Such an item does have a valid downlink in its `ctid` field, however.

For more details about the structure of B-tree indexes, see [Section 64.4.1](#). For more details about deduplication and posting lists, see [Section 64.4.3](#).

`bt_page_items(page bytea)` returns `setof record`

It is also possible to pass a page to `bt_page_items` as a `bytea` value. A page image obtained with `get_raw_page` should be passed as argument. So the last example could also be rewritten like this:

```
test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data, dead, htid, tids[0:2] AS
some_tids
      FROM bt_page_items(get_raw_page('tenk2_hundred', 5));
 itemoffset |   ctid   | itemlen | nulls | vars |          data          | dead |
 htid  |   some_tids
-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+
          | 1 | (16,1) | 16 | f | f | 30 00 00 00 00 00 00 00 |  |
          | 2 | (16,8292) | 616 | f | f | 24 00 00 00 00 00 00 00 | f |
(1,6) | {"(1,6)","(10,22)"}
          | 3 | (16,8292) | 616 | f | f | 25 00 00 00 00 00 00 00 | f |

(13 rows)

All the other details are the same as explained in the previous item.

## F.36.4. BRIN Functions

`brin_page_type(page bytea)` returns text

`brin_page_type` returns the page type of the given BRIN index page, or throws an error if the page is not a valid BRIN page. For example:

```
test=# SELECT brin_page_type(get_raw_page('brinidx', 0));
brin_page_type
-----
meta
```

`brin_metapage_info(page bytea)` returns record

`brin_metapage_info` returns assorted information about a BRIN index metapage. For example:

```
test=# SELECT * FROM brin_metapage_info(get_raw_page('brinidx', 0));
 magic | version | pagesperpage | lastrevmappage
-----+-----+-----+-----
0xA8109CFA | 1 | 4 | 2
```

`brin_revmap_data(page bytea)` returns setof tid

`brin_revmap_data` returns the list of tuple identifiers in a BRIN index range map page. For example:

```
test=# SELECT * FROM brin_revmap_data(get_raw_page('brinidx', 2)) LIMIT 5;
pages
-----
(6,137)
(6,138)
(6,139)
(6,140)
(6,141)
```

`brin_page_items(page bytea, index oid)` returns setof record

`brin_page_items` returns the data stored in the BRIN data page. For example:

```
test=# SELECT * FROM brin_page_items(get_raw_page('brinidx', 5),
                                     'brinidx')
      ORDER BY blknum, attnum LIMIT 6;
 itemoffset | blknum | attnum | allnulls | hasnulls | placeholder | value
-----+-----+-----+-----+-----+-----+-----
137 | 0 | 1 | t | f | f |
137 | 0 | 2 | f | f | f | {1 .. 88}
138 | 4 | 1 | t | f | f |
138 | 4 | 2 | f | f | f | {89 .. 176}
139 | 8 | 1 | t | f | f |
139 | 8 | 2 | f | f | f | {177 .. 264}
```

The returned columns correspond to the fields in the `BrinMemTuple` and `BrinValues` structs.

## F.36.5. GIN Functions

`gin_metapage_info(page bytea)` returns record

`gin_metapage_info` returns information about a GIN index metapage. For example:

Additional Supplied Modules  
and Extensions Shipped in  
postgrespro-ent-14-contrib

```
test=# SELECT * FROM gin_metapage_info(get_raw_page('gin_index', 0));
-[ RECORD 1 ]-----+-----
pending_head      | 4294967295
pending_tail      | 4294967295
tail_free_size    | 0
n_pending_pages   | 0
n_pending_tuples  | 0
n_total_pages     | 7
n_entry_pages     | 6
n_data_pages      | 0
n_entries         | 693
version          | 2
```

gin\_page\_opaque\_info(page bytea) returns record

gin\_page\_opaque\_info returns information about a GIN index opaque area, like the page type. For example:

```
test=# SELECT * FROM gin_page_opaque_info(get_raw_page('gin_index', 2));
 rightlink | maxoff |          flags
-----+-----+-----
          5 |        0 | {data,leaf,compressed}
(1 row)
```

gin\_leafpage\_items(page bytea) returns setof record

gin\_leafpage\_items returns information about the data stored in a GIN leaf page. For example:

```
test=# SELECT first_tid, nbytes, tids[0:5] AS some_tids
       FROM gin_leafpage_items(get_raw_page('gin_test_idx', 2));
 first_tid | nbytes |          some_tids
-----+-----+-----
(8,41)    |    244 | {"(8,41)","(8,43)","(8,44)","(8,45)","(8,46)"}
(10,45)   |    248 | {"(10,45)","(10,46)","(10,47)","(10,48)","(10,49)"}
(12,52)   |    248 | {"(12,52)","(12,53)","(12,54)","(12,55)","(12,56)"}
(14,59)   |    320 | {"(14,59)","(14,60)","(14,61)","(14,62)","(14,63)"}
(167,16)  |    376 | {"(167,16)","(167,17)","(167,18)","(167,19)","(167,20)"}
(170,30)  |    376 | {"(170,30)","(170,31)","(170,32)","(170,33)","(170,34)"}
(173,44)  |    197 | {"(173,44)","(173,45)","(173,46)","(173,47)","(173,48)"}
(7 rows)
```

## F.36.6. GiST Functions

gist\_page\_opaque\_info(page bytea) returns record

gist\_page\_opaque\_info returns information from a GiST index page's opaque area, such as the NSN, rightlink and page type. For example:

```
test=# SELECT * FROM gist_page_opaque_info(get_raw_page('test_gist_idx', 2));
 lsn | nsn | rightlink | flags
-----+-----+-----
 0/1 | 0/0 |          1 | {leaf}
(1 row)
```

gist\_page\_items(page bytea, index\_oid regclass) returns setof record

gist\_page\_items returns information about the data stored in a page of a GiST index. For example:

```
test=# SELECT * FROM gist_page_items(get_raw_page('test_gist_idx', 0),
 'test_gist_idx');
 itemoffset | ctid   | itemlen | dead |          keys
-----+-----+-----+-----+-----
```

Additional Supplied Modules  
and Extensions Shipped in  
postgrespro-ent-14-contrib

```

1 | (1,65535) | 40 | f | (p)=(" (166,166) , (1,1) ")
2 | (2,65535) | 40 | f | (p)=(" (332,332) , (167,167) ")
3 | (3,65535) | 40 | f | (p)=(" (498,498) , (333,333) ")
4 | (4,65535) | 40 | f | (p)=(" (664,664) , (499,499) ")
5 | (5,65535) | 40 | f | (p)=(" (830,830) , (665,665) ")
6 | (6,65535) | 40 | f | (p)=(" (996,996) , (831,831) ")
7 | (7,65535) | 40 | f | (p)=(" (1000,1000) , (997,997) ")
(7 rows)

```

`gist_page_items_bytea(page bytea)` returns setof record

Same as `gist_page_items`, but returns the key data as a raw `bytea` blob. Since it does not attempt to decode the key, it does not need to know which index is involved. For example:

```

test=# SELECT * FROM gist_page_items_bytea(get_raw_page('test_gist_idx', 0));
 itemoffset |   ctid   | itemlen | dead |
key_data
-----+-----+-----+-----+-----

(7 rows)

```

## F.36.7. Hash Functions

`hash_page_type(page bytea)` returns text

`hash_page_type` returns page type of the given HASH index page. For example:

```

test=# SELECT hash_page_type(get_raw_page('con_hash_index', 0));
 hash_page_type
-----
metapage

```

`hash_page_stats(page bytea)` returns setof record

`hash_page_stats` returns information about a bucket or overflow page of a HASH index. For example:

```

test=# SELECT * FROM hash_page_stats(get_raw_page('con_hash_index', 1));
-[ RECORD 1 ]-----
live_items      | 407
dead_items      | 0
page_size       | 8192
free_size       | 8
hasho_prevblkno | 4096
hasho_nextblkno | 8474
hasho_bucket     | 0
hasho_flag       | 66
hasho_page_id    | 65408

```

hash\_page\_items(page bytea) returns setof record

hash\_page\_items returns information about the data stored in a bucket or overflow page of a HASH index page. For example:

```
test=# SELECT * FROM hash_page_items(get_raw_page('con_hash_index', 1)) LIMIT 5;
```

| itemoffset | ctid      | data       |
|------------|-----------|------------|
| 1          | (899,77)  | 1053474816 |
| 2          | (897,29)  | 1053474816 |
| 3          | (894,207) | 1053474816 |
| 4          | (892,159) | 1053474816 |
| 5          | (890,111) | 1053474816 |

hash\_bitmap\_info(index oid, blkno bigint) returns record

hash\_bitmap\_info shows the status of a bit in the bitmap page for a particular overflow page of HASH index. For example:

```
test=# SELECT * FROM hash_bitmap_info('con_hash_index', 2052);
```

| bitmapblkno | bitmapbit | bitstatus |
|-------------|-----------|-----------|
| 65          | 3         | t         |

hash\_metapage\_info(page bytea) returns record

hash\_metapage\_info returns information stored in the meta page of a HASH index. For example:

```
test=# SELECT magic, version, ntuples, ffactor, bsize, bmsize, bmshift,
test-#       maxbucket, highmask, lowmask, ovflpoint, firstfree, nmaps, procid,
test-#       regexp_replace(spares::text, '(.0)*}', '{}') as spares,
test-#       regexp_replace(mapp::text, '(.0)*}', '{}') as mapp
test-# FROM hash_metapage_info(get_raw_page('con_hash_index', 0));
-[ RECORD 1 ]-----
```

|           |                                                                                  |
|-----------|----------------------------------------------------------------------------------|
| magic     | 105121344                                                                        |
| version   | 4                                                                                |
| ntuples   | 500500                                                                           |
| ffactor   | 40                                                                               |
| bsize     | 8152                                                                             |
| bmsize    | 4096                                                                             |
| bmshift   | 15                                                                               |
| maxbucket | 12512                                                                            |
| highmask  | 16383                                                                            |
| lowmask   | 8191                                                                             |
| ovflpoint | 28                                                                               |
| firstfree | 1204                                                                             |
| nmaps     | 1                                                                                |
| procid    | 450                                                                              |
| spares    | {0,0,0,0,0,0,1,1,1,1,1,1,1,1,3,4,4,4,45,55,58,59,508,567,628,704,1193,1202,1204} |
| mapp      | {65}                                                                             |

## F.37. passwordcheck

The passwordcheck module checks users' passwords whenever they are set with [CREATE ROLE](#) or [ALTER ROLE](#) (it doesn't work, if a non-default profile is assigned to the user). If a password is considered too weak, it will be rejected and the command will terminate with an error.

To enable this module, add '\$libdir/passwordcheck' to [shared\\_preload\\_libraries](#) in postgresql.conf, then restart the server.

## Caution

To prevent unencrypted passwords from being sent across the network, written to the server log or otherwise stolen by a database administrator, Postgres Pro allows the user to supply pre-encrypted passwords. Many client programs make use of this functionality and encrypt the password before sending it to the server.

This limits the usefulness of the `passwordcheck` module, because in that case it can only try to guess the password. For this reason, `passwordcheck` is not recommended if your security requirements are high. It is more secure to use an external authentication method such as GSSAPI (see [Chapter 20](#)) than to rely on passwords within the database.

## F.38. pg\_buffercache

The `pg_buffercache` module provides a means for examining what's happening in the shared buffer cache in real time.

The module provides a C function `pg_buffercache_pages` that returns a set of records, plus a view `pg_buffercache` that wraps the function for convenient use.

By default, use is restricted to superusers and members of the `pg_monitor` role. Access may be granted to others using `GRANT`.

### F.38.1. The pg\_buffercache View

The definitions of the columns exposed by the view are shown in [Table F.26](#).

**Table F.26. pg\_buffercache Columns**

| Column Type                                                                                 | Description                                      |
|---------------------------------------------------------------------------------------------|--------------------------------------------------|
| <code>bufferid</code> integer                                                               | ID, in the range 1.. <code>shared_buffers</code> |
| <code>relfilenode</code> oid (references <code>pg_class</code> . <code>relfilenode</code> ) | Filenode number of the relation                  |
| <code>reltablespace</code> oid (references <code>pg_tablespace</code> .oid)                 | Tablespace OID of the relation                   |
| <code>reldatabase</code> oid (references <code>pg_database</code> .oid)                     | Database OID of the relation                     |
| <code>relforknumber</code> smallint                                                         | Fork number within the relation                  |
| <code>relblocknumber</code> bigint                                                          | Page number within the relation                  |
| <code>isdirty</code> boolean                                                                | Is the page dirty?                               |
| <code>usagecount</code> smallint                                                            | Clock-sweep access count                         |
| <code>pinning_backends</code> integer                                                       | Number of backends pinning this buffer           |

There is one row for each buffer in the shared cache. Unused buffers are shown with all fields null except `bufferid`. Shared system catalogs are shown as belonging to database zero.

Because the cache is shared by all the databases, there will normally be pages from relations not belonging to the current database. This means that there may not be matching join rows in `pg_class` for some rows, or that there could even be incorrect joins. If you are trying to join against `pg_class`, it's a good idea to restrict the join to rows having `reldatabase` equal to the current database's OID or zero.

Since buffer manager locks are not taken to copy the buffer state data that the view will display, accessing `pg_buffercache` view has less impact on normal buffer activity but it doesn't provide a consistent set of results across all buffers. However, we ensure that the information of each buffer is self-consistent.

## F.38.2. Sample Output

```
regression=# SELECT n.nspname, c.relname, count(*) AS buffers
              FROM pg_buffercache b JOIN pg_class c
              ON b.relfilenode = pg_relation_filenode(c.oid) AND
                 b.reldatabase IN (0, (SELECT oid FROM pg_database
                                     WHERE datname = current_database()))
              JOIN pg_namespace n ON n.oid = c.relnamespace
              GROUP BY n.nspname, c.relname
              ORDER BY 3 DESC
              LIMIT 10;
```

| nspname    | relname                | buffers |
|------------|------------------------|---------|
| public     | delete_test_table      | 593     |
| public     | delete_test_table_pkey | 494     |
| pg_catalog | pg_attribute           | 472     |
| public     | quad_poly_tbl          | 353     |
| public     | tenk2                  | 349     |
| public     | tenk1                  | 349     |
| public     | gin_test_idx           | 306     |
| pg_catalog | pg_largeobject         | 206     |
| public     | gin_test_tbl           | 188     |
| public     | spgist_text_tbl        | 182     |

Design suggestions: Neil Conway <neilc@samurai.com>

Debugging advice: Tom Lane <tgl@sss.pgh.pa.us>

## F.39. pgcrypto

The `pgcrypto` module provides cryptographic functions for Postgres Pro.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.39.1. General Hashing Functions

#### F.39.1.1. `digest()`

`digest(data text, type text)` returns `bytea`  
`digest(data bytea, type text)` returns `bytea`

Computes a binary hash of the given *data*. *type* is the algorithm to use. Standard algorithms are `md5`, `sha1`, `sha224`, `sha256`, `sha384` and `sha512`. If `pgcrypto` was built with OpenSSL, more algorithms are available, as detailed in [Table F.30](#).

---

If you want the digest as a hexadecimal string, use `encode()` on the result. For example:

```
CREATE OR REPLACE FUNCTION sha1(bytea) returns text AS $$  
    SELECT encode(digest($1, 'sha1'), 'hex')  
$$ LANGUAGE SQL STRICT IMMUTABLE;
```

### F.39.1.2. `hmac()`

`hmac(data text, key text, type text)` returns `bytea`  
`hmac(data bytea, key bytea, type text)` returns `bytea`

Calculates hashed MAC for *data* with key *key*. *type* is the same as in `digest()`.

This is similar to `digest()` but the hash can only be recalculated knowing the key. This prevents the scenario of someone altering data and also changing the hash to match.

If the key is larger than the hash block size it will first be hashed and the result will be used as key.

## F.39.2. Password Hashing Functions

The functions `crypt()` and `gen_salt()` are specifically designed for hashing passwords. `crypt()` does the hashing and `gen_salt()` prepares algorithm parameters for it.

The algorithms in `crypt()` differ from the usual MD5 or SHA1 hashing algorithms in the following respects:

1. They are slow. As the amount of data is so small, this is the only way to make brute-forcing passwords hard.
2. They use a random value, called the *salt*, so that users having the same password will have different encrypted passwords. This is also an additional defense against reversing the algorithm.
3. They include the algorithm type in the result, so passwords hashed with different algorithms can co-exist.
4. Some of them are adaptive — that means when computers get faster, you can tune the algorithm to be slower, without introducing incompatibility with existing passwords.

Table F.27 lists the algorithms supported by the `crypt()` function.

**Table F.27. Supported Algorithms for `crypt()`**

| Algorithm | Max Password Length | Adaptive? | Salt Bits | Output Length | Description                |
|-----------|---------------------|-----------|-----------|---------------|----------------------------|
| bf        | 72                  | yes       | 128       | 60            | Blowfish-based, variant 2a |
| md5       | unlimited           | no        | 48        | 34            | MD5-based crypt            |
| xdes      | 8                   | yes       | 24        | 20            | Extended DES               |
| des       | 8                   | no        | 12        | 13            | Original UNIX crypt        |

### F.39.2.1. `crypt()`

`crypt(password text, salt text)` returns `text`

Calculates a crypt(3)-style hash of *password*. When storing a new password, you need to use `gen_salt()` to generate a new *salt* value. To check a password, pass the stored hash value as *salt*, and test whether the result matches the stored value.

Example of setting a new password:

```
UPDATE ... SET pswhash = crypt('new password', gen_salt('md5'));
```

Example of authentication:

```
SELECT (pswhash = crypt('entered password', pswhash)) AS pswmatch FROM ... ;
```

This returns `true` if the entered password is correct.

### F.39.2.2. `gen_salt()`

`gen_salt(type text [, iter_count integer])` returns text

Generates a new random salt string for use in `crypt()`. The salt string also tells `crypt()` which algorithm to use.

The `type` parameter specifies the hashing algorithm. The accepted types are: `des`, `xdes`, `md5` and `bf`.

The `iter_count` parameter lets the user specify the iteration count, for algorithms that have one. The higher the count, the more time it takes to hash the password and therefore the more time to break it. Although with too high a count the time to calculate a hash may be several years — which is somewhat impractical. If the `iter_count` parameter is omitted, the default iteration count is used. Allowed values for `iter_count` depend on the algorithm and are shown in [Table F.28](#).

**Table F.28. Iteration Counts for `crypt()`**

| Algorithm | Default | Min | Max      |
|-----------|---------|-----|----------|
| xdes      | 725     | 1   | 16777215 |
| bf        | 6       | 4   | 31       |

For `xdes` there is an additional limitation that the iteration count must be an odd number.

To pick an appropriate iteration count, consider that the original DES `crypt` was designed to have the speed of 4 hashes per second on the hardware of that time. Slower than 4 hashes per second would probably dampen usability. Faster than 100 hashes per second is probably too fast.

[Table F.29](#) gives an overview of the relative slowness of different hashing algorithms. The table shows how much time it would take to try all combinations of characters in an 8-character password, assuming that the password contains either only lower case letters, or upper- and lower-case letters and numbers. In the `crypt-bf` entries, the number after a slash is the `iter_count` parameter of `gen_salt`.

**Table F.29. Hash Algorithm Speeds**

| Algorithm  | Hashes/sec | For [a-z]     | For [A-Za-z0-9] | Duration relative to md5 hash |
|------------|------------|---------------|-----------------|-------------------------------|
| crypt-bf/8 | 1792       | 4 years       | 3927 years      | 100k                          |
| crypt-bf/7 | 3648       | 2 years       | 1929 years      | 50k                           |
| crypt-bf/6 | 7168       | 1 year        | 982 years       | 25k                           |
| crypt-bf/5 | 13504      | 188 days      | 521 years       | 12.5k                         |
| crypt-md5  | 171584     | 15 days       | 41 years        | 1k                            |
| crypt-des  | 23221568   | 157.5 minutes | 108 days        | 7                             |
| sha1       | 37774272   | 90 minutes    | 68 days         | 4                             |
| md5 (hash) | 150085504  | 22.5 minutes  | 17 days         | 1                             |

Notes:

- The machine used is an Intel Mobile Core i3.
- `crypt-des` and `crypt-md5` algorithm numbers are taken from John the Ripper v1.6.38 `-test` output.
- `md5 hash` numbers are from `mdcrack` 1.2.
- `sha1` numbers are from `lcrack-20031130-beta`.

- `crypt-bf` numbers are taken using a simple program that loops over 1000 8-character passwords. That way I can show the speed with different numbers of iterations. For reference: `john -test` shows 13506 loops/sec for `crypt-bf/5`. (The very small difference in results is in accordance with the fact that the `crypt-bf` implementation in `pgcrypto` is the same one used in John the Ripper.)

Note that “try all combinations” is not a realistic exercise. Usually password cracking is done with the help of dictionaries, which contain both regular words and various mutations of them. So, even somewhat word-like passwords could be cracked much faster than the above numbers suggest, while a 6-character non-word-like password may escape cracking. Or not.

### F.39.3. PGP Encryption Functions

The functions here implement the encryption part of the OpenPGP ([RFC 4880](#)) standard. Supported are both symmetric-key and public-key encryption.

An encrypted PGP message consists of 2 parts, or *packets*:

- Packet containing a session key — either symmetric-key or public-key encrypted.
- Packet containing data encrypted with the session key.

When encrypting with a symmetric key (i.e., a password):

1. The given password is hashed using a String2Key (S2K) algorithm. This is rather similar to `crypt()` algorithms — purposefully slow and with random salt — but it produces a full-length binary key.
2. If a separate session key is requested, a new random key will be generated. Otherwise the S2K key will be used directly as the session key.
3. If the S2K key is to be used directly, then only S2K settings will be put into the session key packet. Otherwise the session key will be encrypted with the S2K key and put into the session key packet.

When encrypting with a public key:

1. A new random session key is generated.
2. It is encrypted using the public key and put into the session key packet.

In either case the data to be encrypted is processed as follows:

1. Optional data-manipulation: compression, conversion to UTF-8, and/or conversion of line-endings.
2. The data is prefixed with a block of random bytes. This is equivalent to using a random IV.
3. A SHA1 hash of the random prefix and data is appended.
4. All this is encrypted with the session key and placed in the data packet.

#### F.39.3.1. `pgp_sym_encrypt()`

```
pgp_sym_encrypt(data text, psw text [, options text ]) returns bytea
pgp_sym_encrypt_bytea(data bytea, psw text [, options text ]) returns bytea
```

Encrypt *data* with a symmetric PGP key *psw*. The *options* parameter can contain option settings, as described below.

#### F.39.3.2. `pgp_sym_decrypt()`

```
pgp_sym_decrypt(msg bytea, psw text [, options text ]) returns text
pgp_sym_decrypt_bytea(msg bytea, psw text [, options text ]) returns bytea
```

Decrypt a symmetric-key-encrypted PGP message.

Decrypting *bytea* data with `pgp_sym_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_sym_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

### F.39.3.3. `pgp_pub_encrypt()`

`pgp_pub_encrypt(data text, key bytea [, options text])` returns `bytea`  
`pgp_pub_encrypt_bytea(data bytea, key bytea [, options text])` returns `bytea`

Encrypt *data* with a public PGP key *key*. Giving this function a secret key will produce an error.

The *options* parameter can contain option settings, as described below.

### F.39.3.4. `pgp_pub_decrypt()`

`pgp_pub_decrypt(msg bytea, key bytea [, psw text [, options text]])` returns `text`  
`pgp_pub_decrypt_bytea(msg bytea, key bytea [, psw text [, options text]])` returns `bytea`

Decrypt a public-key-encrypted message. *key* must be the secret key corresponding to the public key that was used to encrypt. If the secret key is password-protected, you must give the password in *psw*. If there is no password, but you want to specify options, you need to give an empty password.

Decrypting `bytea` data with `pgp_pub_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_pub_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

### F.39.3.5. `pgp_key_id()`

`pgp_key_id(bytea)` returns `text`

`pgp_key_id` extracts the key ID of a PGP public or secret key. Or it gives the key ID that was used for encrypting the data, if given an encrypted message.

It can return 2 special key IDs:

- `SYMKEY`

The message is encrypted with a symmetric key.

- `ANYKEY`

The message is public-key encrypted, but the key ID has been removed. That means you will need to try all your secret keys on it to see which one decrypts it. `pgcrypto` itself does not produce such messages.

Note that different keys may have the same ID. This is rare but a normal event. The client application should then try to decrypt with each one, to see which fits — like handling `ANYKEY`.

### F.39.3.6. `armor()`, `dearmor()`

`armor(data bytea [, keys text[], values text[]])` returns `text`  
`dearmor(data text)` returns `bytea`

These functions wrap/unwrap binary data into PGP ASCII-armor format, which is basically Base64 with CRC and additional formatting.

If the *keys* and *values* arrays are specified, an *armor header* is added to the armored format for each key/value pair. Both arrays must be single-dimensional, and they must be of the same length. The keys and values cannot contain any non-ASCII characters.

### F.39.3.7. `pgp_armor_headers`

`pgp_armor_headers(data text, key out text, value out text)` returns `setof record`

`pgp_armor_headers()` extracts the armor headers from *data*. The return value is a set of rows with two columns, key and value. If the keys or values contain any non-ASCII characters, they are treated as UTF-8.

### F.39.3.8. Options for PGP Functions

Options are named to be similar to GnuPG. An option's value should be given after an equal sign; separate options from each other with commas. For example:

```
pgp_sym_encrypt(data, psw, 'compress-algo=1, cipher-algo=aes256')
```

All of the options except `convert-crlf` apply only to encrypt functions. Decrypt functions get the parameters from the PGP data.

The most interesting options are probably `compress-algo` and `unicode-mode`. The rest should have reasonable defaults.

#### F.39.3.8.1. cipher-algo

Which cipher algorithm to use.

Values: bf, aes128, aes192, aes256 (OpenSSL-only: 3des, cast5)

Default: aes128

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

#### F.39.3.8.2. compress-algo

Which compression algorithm to use. Only available if Postgres Pro was built with zlib.

Values:

0 - no compression

1 - ZIP compression

2 - ZLIB compression (= ZIP plus meta-data and block CRCs)

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

#### F.39.3.8.3. compress-level

How much to compress. Higher levels compress smaller but are slower. 0 disables compression.

Values: 0, 1-9

Default: 6

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

#### F.39.3.8.4. convert-crlf

Whether to convert `\n` into `\r\n` when encrypting and `\r\n` to `\n` when decrypting. RFC 4880 specifies that text data should be stored using `\r\n` line-feeds. Use this to get fully RFC-compliant behavior.

Values: 0, 1

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`, `pgp_sym_decrypt`, `pgp_pub_decrypt`

#### F.39.3.8.5. disable-mdc

Do not protect data with SHA-1. The only good reason to use this option is to achieve compatibility with ancient PGP products, predating the addition of SHA-1 protected packets to RFC 4880. Recent gnupg.org and pgp.com software supports it fine.

Values: 0, 1

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

#### F.39.3.8.6. sess-key

Use separate session key. Public-key encryption always uses a separate session key; this option is for symmetric-key encryption, which by default uses the S2K key directly.

Values: 0, 1

Default: 0

Applies to: pgp\_sym\_encrypt

#### **F.39.3.8.7. s2k-mode**

Which S2K algorithm to use.

Values:

0 - Without salt. Dangerous!

1 - With salt but with fixed iteration count.

3 - Variable iteration count.

Default: 3

Applies to: pgp\_sym\_encrypt

#### **F.39.3.8.8. s2k-count**

The number of iterations of the S2K algorithm to use. It must be a value between 1024 and 65011712, inclusive.

Default: A random value between 65536 and 253952

Applies to: pgp\_sym\_encrypt, only with s2k-mode=3

#### **F.39.3.8.9. s2k-digest-algo**

Which digest algorithm to use in S2K calculation.

Values: md5, sha1

Default: sha1

Applies to: pgp\_sym\_encrypt

#### **F.39.3.8.10. s2k-cipher-algo**

Which cipher to use for encrypting separate session key.

Values: bf, aes, aes128, aes192, aes256

Default: use cipher-algo

Applies to: pgp\_sym\_encrypt

#### **F.39.3.8.11. unicode-mode**

Whether to convert textual data from database internal encoding to UTF-8 and back. If your database already is UTF-8, no conversion will be done, but the message will be tagged as UTF-8. Without this option it will not be.

Values: 0, 1

Default: 0

Applies to: pgp\_sym\_encrypt, pgp\_pub\_encrypt

### **F.39.3.9. Generating PGP Keys with GnuPG**

To generate a new key:

```
gpg --gen-key
```

The preferred key type is “DSA and Elgamal”.

For RSA encryption you must create either DSA or RSA sign-only key as master and then add an RSA encryption subkey with `gpg --edit-key`.

To list keys:

```
gpg --list-secret-keys
```

To export a public key in ASCII-armor format:

```
gpg -a --export KEYID > public.key
```

To export a secret key in ASCII-armor format:

```
gpg -a --export-secret-keys KEYID > secret.key
```

You need to use `dearmor()` on these keys before giving them to the PGP functions. Or if you can handle binary data, you can drop `-a` from the command.

For more details see `man gpg`, *The GNU Privacy Handbook* and other documentation on <https://www.gnupg.org/>.

### F.39.3.10. Limitations of PGP Code

- No support for signing. That also means that it is not checked whether the encryption subkey belongs to the master key.
- No support for encryption key as master key. As such practice is generally discouraged, this should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with `pgcrypto`, but create new ones, as the usage scenario is rather different.

### F.39.4. Raw Encryption Functions

These functions only run a cipher over data; they don't have any advanced features of PGP encryption. Therefore they have some major problems:

1. They use user key directly as cipher key.
2. They don't provide any integrity checking, to see if the encrypted data was modified.
3. They expect that users manage all encryption parameters themselves, even IV.
4. They don't handle text.

So, with the introduction of PGP encryption, usage of raw encryption functions is discouraged.

```
encrypt(data bytea, key bytea, type text) returns bytea  
decrypt(data bytea, key bytea, type text) returns bytea
```

```
encrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea  
decrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
```

Encrypt/decrypt data using the cipher method specified by *type*. The syntax of the *type* string is:

```
algorithm [ - mode ] [ /pad: padding ]
```

where *algorithm* is one of:

- `bf` — Blowfish
- `aes` — AES (Rijndael-128, -192 or -256)

and *mode* is one of:

- `cbc` — next block depends on previous (default)
- `ecb` — each block is encrypted separately (for testing only)

and *padding* is one of:

- `pkcs` — data may be any length (default)
- `none` — data must be multiple of cipher block size

So, for example, these are equivalent:

```
encrypt(data, 'fooz', 'bf')  
encrypt(data, 'fooz', 'bf-cbc/pad:pkcs')
```

In `encrypt_iv` and `decrypt_iv`, the `iv` parameter is the initial value for the CBC mode; it is ignored for ECB. It is clipped or padded with zeroes if not exactly block size. It defaults to all zeroes in the functions without this parameter.

## F.39.5. Random-Data Functions

`gen_random_bytes(count integer)` returns `bytea`

Returns `count` cryptographically strong random bytes. At most 1024 bytes can be extracted at a time. This is to avoid draining the randomness generator pool.

`gen_random_uuid()` returns `uuid`

Returns a version 4 (random) UUID. (Obsolete, this function internally calls the [core function](#) of the same name.)

## F.39.6. Notes

### F.39.6.1. Configuration

`pgcrypto` configures itself according to the findings of the main Postgres Pro `configure` script. The options that affect it are `--with-zlib` and `--with-ssl=openssl`.

When compiled with `zlib`, PGP encryption functions are able to compress data before encrypting.

When compiled with `OpenSSL`, there will be more algorithms available. Also public-key encryption functions will be faster as `OpenSSL` has more optimized `BIGNUM` functions.

**Table F.30. Summary of Functionality with and without OpenSSL**

| Functionality             | Built-in | With OpenSSL |
|---------------------------|----------|--------------|
| MD5                       | yes      | yes          |
| SHA1                      | yes      | yes          |
| SHA224/256/384/512        | yes      | yes          |
| Other digest algorithms   | no       | yes (Note 1) |
| Blowfish                  | yes      | yes          |
| AES                       | yes      | yes          |
| DES/3DES/CAST5            | no       | yes          |
| Raw encryption            | yes      | yes          |
| PGP Symmetric encryption  | yes      | yes          |
| PGP Public-Key encryption | yes      | yes          |

When compiled against `OpenSSL` 3.0.0 and later versions, the legacy provider must be activated in the `openssl.cnf` configuration file in order to use older ciphers like DES or Blowfish.

Notes:

1. Any digest algorithm `OpenSSL` supports is automatically picked up. This is not possible with ciphers, which need to be supported explicitly.

### F.39.6.2. NULL Handling

As is standard in SQL, all functions return `NULL`, if any of the arguments are `NULL`. This may create security risks on careless usage.

### F.39.6.3. Security Limitations

All `pgcrypto` functions run inside the database server. That means that all the data and passwords move between `pgcrypto` and client applications in clear text. Thus you must:

1. Connect locally or use SSL connections.
2. Trust both system and database administrator.

If you cannot, then better do crypto inside client application.

The implementation does not resist *side-channel attacks*. For example, the time required for a `pgcrypto` decryption function to complete varies among ciphertexts of a given size.

## F.39.7. Author

Marko Kreen <markokr@gmail.com>

`pgcrypto` uses code from the following sources:

| Algorithm         | Author                  | Source origin                 |
|-------------------|-------------------------|-------------------------------|
| DES crypt         | David Burren and others | FreeBSD libcrypt              |
| MD5 crypt         | Poul-Henning Kamp       | FreeBSD libcrypt              |
| Blowfish crypt    | Solar Designer          | www.openwall.com              |
| Blowfish cipher   | Simon Tatham            | PuTTY                         |
| Rijndael cipher   | Brian Gladman           | OpenBSD sys/crypto            |
| MD5 hash and SHA1 | WIDE Project            | KAME kame/sys/crypto          |
| SHA256/384/512    | Aaron D. Gifford        | OpenBSD sys/crypto            |
| BIGNUM math       | Michael J. Fromberger   | dartmouth.edu/~sting/sw/imath |

## F.40. pg\_freespacemap

The `pg_freespacemap` module provides a means for examining the free space map (FSM). It provides a function called `pg_freespace`, or two overloaded functions, to be precise. The functions show the value recorded in the free space map for a given page, or for all pages in the relation.

By default use is restricted to superusers and members of the `pg_stat_scan_tables` role. Access may be granted to others using `GRANT`.

### F.40.1. Functions

`pg_freespace(rel regclass IN, blkno bigint IN) returns int2`

Returns the amount of free space on the page of the relation, specified by `blkno`, according to the FSM.

`pg_freespace(rel regclass IN, blkno OUT bigint, avail OUT int2)`

Displays the amount of free space on each page of the relation, according to the FSM. A set of (`blkno bigint`, `avail int2`) tuples is returned, one tuple for each page in the relation.

`pg_freespace_relation_logical_blocks(relation regclass [, fork text ]) returns bigint`

Computes the disk space used by one fork of the specified relation in blocks (pages). Use the `fork` parameter to specify which fork to examine. Possible values:

- `main` returns the size of the main data fork of the relation.
- `fsm` returns the size of the Free Space Map (see [Section 70.3](#)) associated with the relation.
- `vm` returns the size of the Visibility Map (see [Section 70.4](#)) associated with the relation.

## Note

The `init` value will always return 0, as the `init` fork is not associated with the disk.

If `fork` is omitted, the function will return the size of the main data fork of the relation.

This function returns correct results independent of whether the table is compressed or not.

The values stored in the free space map are not exact. They're rounded to precision of 1/256th of `BLCKSZ` (32 bytes with default `BLCKSZ`), and they're not kept fully up-to-date as tuples are inserted and updated.

For indexes, what is tracked is entirely-unused pages, rather than free space within pages. Therefore, the values are not meaningful, just whether a page is in-use or empty.

## F.40.2. Sample Output

```
postgres=# SELECT * FROM pg_freespace('foo');
```

| blkno | avail |
|-------|-------|
| 0     | 0     |
| 1     | 0     |
| 2     | 0     |
| 3     | 32    |
| 4     | 704   |
| 5     | 704   |
| 6     | 704   |
| 7     | 1216  |
| 8     | 704   |
| 9     | 704   |
| 10    | 704   |
| 11    | 704   |
| 12    | 704   |
| 13    | 704   |
| 14    | 704   |
| 15    | 704   |
| 16    | 704   |
| 17    | 704   |
| 18    | 704   |
| 19    | 3648  |

(20 rows)

```
postgres=# SELECT * FROM pg_freespace('foo', 7);
```

| pg_freespace |
|--------------|
| 1216         |

(1 row)

Original version by Mark Kirkwood <markir@paradise.net.nz>. Rewritten in version 8.4 to suit new FSM implementation by Heikki Linnakangas <heikki@enterprisedb.com>

## F.41. pg\_hint\_plan

### F.41.1. Description

`pg_hint_plan` is a module that allows a user to control an execution plan with hinting phrases mentioned in comments of a special form.

Postgres Pro Enterprise uses a cost-based optimizer, which utilizes data statistics rather than static rules. The planner (optimizer) estimates costs of all possible execution plans for an SQL statement, then the execution plan with the lowest cost is executed. The planner makes every effort to select the best execution plan, but it is not always perfect, since it does not take into account some of the data properties or correlations between columns.

`pg_hint_plan` makes it possible to tweak execution plans using so-called “hints”, which are simple descriptions added in SQL comments of a special form.

## F.41.2. Overview

### F.41.2.1. Basic Usage

`pg_hint_plan` reads hinting phrases in comments of a special form given with the target SQL statement. The special comment begins with the character sequence `/*+` and ends with `*/`. Hinting phrases consist of a hint name and following parameters enclosed in parentheses and delimited by whitespaces. Each hinting phrase can be delimited by new lines for readability.

In the example below, a hash join is selected as a joining method and `pgbench_accounts` is scanned by a sequential scan method.

```
/*+
  HashJoin(a b)
  SeqScan(a)
*/
EXPLAIN SELECT *
  FROM pgbench_branches b
  JOIN pgbench_accounts a ON b.bid = a.bid
  ORDER BY a.aid;

                                QUERY PLAN
-----
Sort  (cost=31465.84..31715.84 rows=100000 width=197)
  Sort Key: a.aid
    -> Hash Join  (cost=1.02..4016.02 rows=100000 width=197)
      Hash Cond: (a.bid = b.bid)
        -> Seq Scan on pgbench_accounts a  (cost=0.00..2640.00 rows=100000 width=97)
        -> Hash  (cost=1.01..1.01 rows=1 width=100)
          -> Seq Scan on pgbench_branches b  (cost=0.00..1.01 rows=1 width=100)

(7 rows)
```

### F.41.3. Hint Table

The above section mentions that hints are inserted in a comment of a special form. This is inconvenient if a query cannot be edited. For such cases, hints can be placed in a special table called `hint_plan.hints`, which looks as follows:

| Column                         | Description                                                                                                                                                                                                                             |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>id</code>                | A unique number to identify a row for a hint. This column is filled automatically by sequence.                                                                                                                                          |
| <code>norm_query_string</code> | A pattern that matches the query to be hinted. Constants in the query should be replaced with <code>?</code> as in the example below. Whitespaces are significant in the pattern.                                                       |
| <code>application_name</code>  | A value of <code>application_name</code> of sessions to apply the hint to. The hint in the example below applies to sessions connected from <code>psql</code> . An empty string means sessions with any <code>application_name</code> . |

| Column | Description                                                                        |
|--------|------------------------------------------------------------------------------------|
| hint   | A hint phrase. This must be a series of hints excluding surrounding comment marks. |

The following example shows how to work with the hint table.

```
INSERT INTO hint_plan.hints(norm_query_string, application_name, hints)
VALUES (
    'EXPLAIN (COSTS false) SELECT * FROM t1 WHERE t1.id = ?;',
    '',
    'SeqScan(t1) ');
INSERT 0 1
UPDATE hint_plan.hints
SET hints = 'IndexScan(t1) '
WHERE id = 1;
UPDATE 1
DELETE FROM hint_plan.hints
WHERE id = 1;
DELETE 1
```

The hint table is owned by the extension owner and has the same default privileges as at the time of its creation, i.e. during `CREATE EXTENSION`. Hints in the hint table take priority over the hints specified in comments.

### F.41.3.1. Types of Hints

Hinting phrases are classified into several types depending on the kind of object and how they can affect the planner. For more details, see [Section F.41.9](#).

#### F.41.3.1.1. Hints for Scan Methods

Scan method hints enforce a specific scanning method on the target table. `pg_hint_plan` recognizes the target table by alias names, if any. They are, for example, `SeqScan` or `IndexScan`.

Scan hints work with ordinary tables, inheritance tables, `UNLOGGED` tables, temporary tables, and system catalogs. External (foreign) tables, table functions, `VALUES` clause, CTEs, views, and subqueries are not affected.

```
/*+
    SeqScan(t1)
    IndexScan(t2 t2_pkey)
*/
SELECT * FROM table1 t1 JOIN table2 t2 ON (t1.key = t2.key);
```

#### F.41.3.1.2. Hints for Join Methods

Join method hints enforce join methods of the joins involving the specified tables.

This can affect joins only on ordinary tables. Inheritance tables, `UNLOGGED` tables, temporary tables, external (foreign) tables, system catalogs, table functions, `VALUES` command results, and CTEs are allowed to be in the parameter list. Joins on views and subqueries are not affected.

Join method hints are recommended to be used together with the `Leading` joining order hint because it guarantees that a joining order specified in the request will be executed.

The hint below prompts the `NestLoop(MergeJoin(c b) a)` joining structure:

```
/*+ Leading(((c b) a)) MergeJoin(c b) NestLoop(a b c) */ EXPLAIN(COSTS OFF, TIMING OFF,
SUMMARY OFF)
SELECT count(*) FROM t1 a, t1 b, t1 c WHERE a.f1 = b.f1 AND b.f1 = c.f1;
```

QUERY PLAN

```
-----  
Aggregate  
->  Nested Loop  
      ->  Merge Join  
            Merge Cond: (c.f1 = b.f1)  
            ->  Index Only Scan using t1_idx1 on t1 c  
            ->  Materialize  
                  ->  Index Only Scan using t1_idx1 on t1 b  
      ->  Memoize  
            Cache Key: b.f1  
            Cache Mode: logical  
            ->  Index Only Scan using t1_idx1 on t1 a  
                  Index Cond: (f1 = b.f1)
```

#### F.41.3.1.3. Hint for Joining Order

The `Leading` hint enforces the joining order for two or more tables. There are two ways of enforcing. One is enforcing specific joining order but not restricting direction at each join level:

```
/*+  
    NestLoop(t1 t2)  
    MergeJoin(t1 t2 t3)  
    Leading(t1 t2 t3)  
*/  
SELECT * FROM table1 t1  
    JOIN table table2 t2 ON (t1.key = t2.key)  
    JOIN table table3 t3 ON (t2.key = t3.key);
```

Another way also enforces join direction. When the above join order is specified, the join direction chosen by the planner (outer table — inner table) may be different from the expected one. If you want to change the join direction in such a situation, use the following format:

```
/*+ Leading ((t1 (t2 t3))) * / SELECT ...
```

In this format, two elements enclosed in parentheses are nested, and within one parenthesis, the first element is the outer table, and the second element is the inner table.

Note that the `Leading` hint (just like join methods) does not operate together with [GEQO](#) if the number of tables specified in the request exceeds `geqo_threshold`.

Some extra examples of using the hint for joining order:

```
/*+ Leading(((c b) a)) */ EXPLAIN (COSTS OFF, TIMING OFF, SUMMARY OFF)  
SELECT count(*) FROM t1 a, t1 b, t1 c WHERE a.f1 = b.f1 AND b.f1 = c.f1;  
QUERY PLAN
```

```
-----  
Aggregate  
->  Hash Join  
      Hash Cond: (b.f1 = a.f1)  
      ->  Nested Loop  
            ->  Index Only Scan using t1_idx1 on t1 c  
            ->  Memoize  
                  Cache Key: c.f1  
                  Cache Mode: logical  
                  ->  Index Only Scan using t1_idx1 on t1 b  
                        Index Cond: (f1 = c.f1)  
      ->  Hash  
            ->  Seq Scan on t1 a
```

And an example below:

```
/*+ Leading(((d c) (b a))) */ EXPLAIN (COSTS OFF, TIMING OFF, SUMMARY OFF)
SELECT count(*) FROM t1 a, t1 b, t1 c, t1 d WHERE a.f1 = b.f1 AND b.f1 = c.f1 AND c.f1
= d.f1;
```

QUERY PLAN

```
-----
Aggregate
-> Hash Join
    Hash Cond: (c.f1 = a.f1)
-> Nested Loop
    -> Index Only Scan using t1_idx1 on t1 d
    -> Memoize
        Cache Key: d.f1
        Cache Mode: logical
    -> Index Only Scan using t1_idx1 on t1 c
        Index Cond: (f1 = d.f1)
-> Hash
    -> Hash Join
        Hash Cond: (b.f1 = a.f1)
    -> Seq Scan on t1 b
    -> Hash
        -> Seq Scan on t1 a
```

For details, see [Section F.41.9](#).

#### F.41.3.1.4. Hints for Controlling Join Behavior

The “Memoize” hint allows the join to memoize the inner result, and the “NoMemoize” hint disallows it. In the example below, the “NoMemoize” hint prohibits the topmost hash join from memoizing the result of the table a.

```
/*+ NoMemoize(a b) */
EXPLAIN SELECT * FROM a, b WHERE a.val = b.val;
```

QUERY PLAN

```
-----
Hash Join  (cost=270.00..1412.50 rows=100000 width=16)
  Hash Cond: (b.val = a.val)
-> Seq Scan on b  (cost=0.00..15.00 rows=1000 width=8)
-> Hash  (cost=145.00..145.00 rows=10000 width=8)
    -> Seq Scan on a  (cost=0.00..145.00 rows=10000 width=8)
```

#### F.41.3.1.5. Hint for Row Number Correction

The `Rows` hint corrects the row number misestimation of joins that comes from restrictions in the planner. For example:

```
/*+ Rows(a b #10) */ SELECT... ; Sets rows of join result to 10
/*+ Rows(a b +10) */ SELECT... ; Increments row number by 10
/*+ Rows(a b -10) */ SELECT... ; Subtracts 10 from the row number.
/*+ Rows(a b *10) */ SELECT... ; Makes the number 10 times larger.
```

#### F.41.3.1.6. Hint for Parallel Plans

The `Parallel` hint enforces parallel execution configuration on scans. The third parameter specifies the strength of enforcement. “soft” means that `pg_hint_plan` only changes `max_parallel_workers_per_gather` and leaves all others to the planner. “hard” changes other planner parameters so as to forcibly apply the number. This can affect ordinary tables, inheritance parents, `UNLOGGED` tables, and system catalog. External tables, table functions, `VALUES` clause, CTEs, views, and subqueries are not affected. Internal tables of a view can be specified by its real name or its alias as the target object. The following example shows that the query is enforced differently on each table.

Additional Supplied Modules  
and Extensions Shipped in  
postgrespro-ent-14-contrib

---

```
EXPLAIN /*+ Parallel(c1 3 hard) Parallel(c2 5 hard) */
        SELECT c2.a FROM c1 JOIN c2 ON (c1.a = c2.a);
        QUERY PLAN
```

---

```
Hash Join  (cost=2.86..11406.38 rows=101 width=4)
  Hash Cond: (c1.a = c2.a)
    -> Gather  (cost=0.00..7652.13 rows=1000101 width=4)
        Workers Planned: 3
        -> Parallel Seq Scan on c1  (cost=0.00..7652.13 rows=322613 width=4)
    -> Hash  (cost=1.59..1.59 rows=101 width=4)
        -> Gather  (cost=0.00..1.59 rows=101 width=4)
            Workers Planned: 5
            -> Parallel Seq Scan on c2  (cost=0.00..1.59 rows=59 width=4)
```

```
EXPLAIN /*+ Parallel(t1 5 hard) */ SELECT sum(a) FROM t1;
        QUERY PLAN
```

---

```
Finalize Aggregate  (cost=693.02..693.03 rows=1 width=8)
  -> Gather  (cost=693.00..693.01 rows=5 width=8)
      Workers Planned: 5
      -> Partial Aggregate  (cost=693.00..693.01 rows=1 width=8)
          -> Parallel Seq Scan on t1  (cost=0.00..643.00 rows=20000 width=4)
```

#### F.41.3.1.7. Hints for Stored Procedures

Hints can be used with stored procedures. Be careful when using hints, since they can be inherited.

```
CREATE OR REPLACE FUNCTION test_1() RETURNS bool AS $$
BEGIN
EXECUTE 'SELECT count(*) FROM t1 WHERE f1 < 2' ;
RETURN true;
END; $$ language plpgsql;
```

```
CREATE OR REPLACE FUNCTION test_2() RETURNS void AS $$
BEGIN
EXECUTE 'SELECT /*+ SET(enable_bitmapscan off)*/ test_1()' ;
END;
$$ language plpgsql;
```

```
SELECT test_2();
```

```
Query Text: SELECT count(*) FROM t1 WHERE f1 < 2
Aggregate  (cost=18.00..18.01 rows=1 width=8) (actual time=0.511..0.512 rows=1
loops=1)
  -> Seq Scan on t1  (cost=0.00..17.50 rows=200 width=0) (actual time=0.105..0.457
rows=200 loops=1)
    Filter: (f1 < 2)
    Rows Removed by Filter: 800
```

#### F.41.3.1.8. Hints for Prepared Statements

The `pg_hint_plan` extension allows using hints with prepared statements. Hints should be specified in the `PREPARE` statement and are ignored in the `EXECUTE` statement.

Below are a couple of sample queries. With the `IndexOnlyScan(t1)` hint:

```
/*+ IndexOnlyScan(t1) */ PREPARE stmt AS SELECT count(*) FROM t1 WHERE f1 < 2;

EXPLAIN EXECUTE stmt;
EXPLAIN (COSTS OFF, TIMING OFF, SUMMARY OFF) EXECUTE stmt;
```

QUERY PLAN

```
Aggregate
->  Index Only Scan using t1_idx1 on t1
    Index Cond: (f1 < 2)
```

And with the `BitmapScan(t1)` hint:

```
/*+ BitmapScan(t1) */ EXPLAIN (COSTS OFF, TIMING OFF, SUMMARY OFF) EXECUTE stmt;
QUERY PLAN
```

```
Aggregate
->  Index Only Scan using t1_idx1 on t1
    Index Cond: (f1 < 2)
```

#### F.41.3.1.9. Setting GUC Parameters During Planning

The `Set` hint changes GUC parameters during planning. The GUC parameter shown in [Section 19.7.2](#) can have the expected effects on planning unless any other hint conflicts with the planner method configuration parameters. When multiple hints change the same GUC, the last hint takes effect. GUC parameters for `pg_hint_plan` are also settable by this hint, but it may not work as you expect.

```
/*+ Set(random_page_cost 2.0) */
SELECT * FROM table1 t1 WHERE key = 'value';
...
```

#### F.41.3.2. GUC Parameters for `pg_hint_plan`

GUC parameters described below affect the behavior of `pg_hint_plan`.

**Table F.31. GUC Parameters**

| Parameter Name                              | Description                                                                                                                                                                                 | Default Value |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| <code>pg_hint_plan.enable_hint</code>       | True enables <code>pg_hint_plan</code> .                                                                                                                                                    | on            |
| <code>pg_hint_plan.enable_hint_table</code> | True enables hinting by table.                                                                                                                                                              | off           |
| <code>pg_hint_plan.parse_messages</code>    | Specifies the log level of hint parse error. Valid values are <code>error</code> , <code>warning</code> , <code>notice</code> , <code>info</code> , <code>log</code> , <code>debug</code> . | info          |
| <code>pg_hint_plan.debug_print</code>       | Controls debug print and verbosity. Valid values are <code>off</code> , <code>on</code> , <code>detailed</code> , and <code>verbose</code> .                                                | off           |
| <code>pg_hint_plan.message_level</code>     | Specifies message level of debug print. Valid values are <code>error</code> , <code>warning</code> , <code>notice</code> , <code>info</code> , <code>log</code> , <code>debug</code> .      | log           |
| <code>pg_hint_plan.hints_anywhere</code>    | If it is <code>on</code> , <code>pg_hint_plan</code> reads hints ignoring SQL syntax. This allows placing hints anywhere in the query but may cause false reads.                            | off           |

#### F.41.4. Installation

The `pg_hint_plan` extension is provided together with Postgres Pro Enterprise as a separate pre-built package. For detailed package installation instructions, see [Chapter 17](#). Once you have Postgres Pro Enterprise installed, activate `pg_hint_plan`:

```
LOAD 'pg_hint_plan';  
LOAD
```

You can also load it globally by adding `pg_hint_plan` to the `shared_preload_libraries` parameter in the `postgresql.conf` file.

```
shared_preload_libraries = 'pg_hint_plan'
```

For automatic loading for specific sessions, use `ALTER USER SET/ALTER DATABASE SET`.

`pg_hint_plan` does not require `CREATE EXTENSION`, but if you plan to use the hint table, create the extension and enable the `enable_hint_table` parameter:

```
CREATE EXTENSION pg_hint_plan;  
SET pg_hint_plan.enable_hint_table TO on;
```

## F.41.5. Details in Hinting

### F.41.5.1. Syntax and Placement

`pg_hint_plan` reads hints only from the first block comment and immediately stops parsing of any characters except alphabetical characters, digits, spaces, underscores, commas, and parentheses. In the following example `HashJoin(a b)` and `SeqScan(a)` are parsed as hints, but `IndexScan(a)` and `MergeJoin(a b)` are not:

```
/*+  
    HashJoin(a b)  
    SeqScan(a)  
*/  
/*+ IndexScan(a) */  
EXPLAIN SELECT /*+ MergeJoin(a b) */ *  
    FROM pgbench_branches b  
    JOIN pgbench_accounts a ON b.bid = a.bid  
    ORDER BY a.aid;  
  
                                QUERY PLAN  
-----  
Sort  (cost=31465.84..31715.84 rows=100000 width=197)  
  Sort Key: a.aid  
    -> Hash Join  (cost=1.02..4016.02 rows=100000 width=197)  
          Hash Cond: (a.bid = b.bid)  
            -> Seq Scan on pgbench_accounts a  (cost=0.00..2640.00 rows=100000 width=97)  
            -> Hash  (cost=1.01..1.01 rows=1 width=100)  
                  -> Seq Scan on pgbench_branches b  (cost=0.00..1.01 rows=1 width=100)  
(7 rows)
```

However, when the `hints_anywhere` parameter is on, `pg_hint_plan` reads hints from anywhere in the query so the following hint uses would be equivalent:

```
EXPLAIN /*+ SeqScan(t1) */  
SELECT * FROM table1 t1 WHERE a < 10;  
  
                                QUERY PLAN  
-----  
Seq Scan on table1 t1  (cost=0.00..17.50 rows=9 width=8)  
  Filter: (a < 10)  
(2 rows)  
  
EXPLAIN  
SELECT * FROM table1 t1 WHERE a < 10 AND '/*+SeqScan(t1) */' <> '';
```

QUERY PLAN

```
-----  
Seq Scan on table1 t1  (cost=0.00..17.50 rows=9 width=8)  
  Filter: (a < 10)  
(2 rows)
```

EXPLAIN

```
SELECT * FROM table1 t1 WHERE a < 10 /*+SeqScan(t1)*/;  
                                QUERY PLAN
```

```
-----  
Seq Scan on table1 t1  (cost=0.00..17.50 rows=9 width=8)  
  Filter: (a < 10)  
(2 rows)
```

### F.41.5.2. Using with PL/pgSQL

`pg_hint_plan` works for queries in PL/pgSQL scripts with some restrictions.

- Hints affect only the following kinds of queries:
  - Queries that return one row (`SELECT`, `INSERT`, `UPDATE`, and `DELETE`)
  - Queries that return multiple rows (`RETURN QUERY`)
  - Dynamic SQL statements (`EXECUTE`)
  - Cursor open (`OPEN`)
  - Loop over result of a query (`FOR`)
- A hint comment should be placed after the first word in a query as in the example below, since preceding comments are not sent as a part of the query.

```
CREATE FUNCTION hints_func(integer) RETURNS integer AS $$  
DECLARE  
    id integer;  
    cnt integer;  
BEGIN  
    SELECT /*+ NoIndexScan(a) */ aid  
        INTO id FROM pgbench_accounts a WHERE aid = $1;  
    SELECT /*+ SeqScan(a) */ count(*)  
        INTO cnt FROM pgbench_accounts a;  
    RETURN id + cnt;  
END;  
$$ LANGUAGE plpgsql;
```

### F.41.5.3. Letter Case in Object Names

Unlike the way PostgreSQL handles object names, `pg_hint_plan` compares bare object names in hints against the database internal object names in a case-sensitive manner. Therefore, an object name `TBL` in a hint matches only "TBL" in database and does not match any unquoted names like `TBL`, `tbl`, or `TbL`.

### F.41.5.4. Escaping Special Characters in Object Names

The objects defined as the hint parameter should be enclosed in double quotes if they include parentheses, double quotes, and whitespaces. The escaping rules are the same as in PostgreSQL.

### F.41.5.5. Distinction Between Multiple Occurrences of a Table

`pg_hint_plan` identifies the target object by using aliases if they exist. This behavior is useful to point at a specific occurrence among multiple occurrences of one table.

```

/*+ HashJoin(t1 t1) */
EXPLAIN SELECT * FROM s1.t1
  JOIN public.t1 ON (s1.t1.id=public.t1.id);
INFO:  hint syntax error at or near "HashJoin(t1 t1)"
DETAIL:  Relation name "t1" is ambiguous.
...
/*+ HashJoin(pt st) */
EXPLAIN SELECT * FROM s1.t1 st
  JOIN public.t1 pt ON (st.id=pt.id);
                                QUERY PLAN
-----
Hash Join  (cost=64.00..1112.00 rows=28800 width=8)
  Hash Cond: (st.id = pt.id)
    -> Seq Scan on t1 st  (cost=0.00..34.00 rows=2400 width=4)
    -> Hash  (cost=34.00..34.00 rows=2400 width=4)
        -> Seq Scan on t1 pt  (cost=0.00..34.00 rows=2400 width=4)

```

#### F.41.5.6. Underlying Tables of Views or Rules

Hints are not applicable on views themselves, but they can affect the queries within the view if the object names match the object names in the expanded query on the view. Assigning aliases to the tables in the view enables them to be manipulated from outside of the view.

```

CREATE VIEW v1 AS SELECT * FROM t2;
EXPLAIN /*+ HashJoin(t1 v1) */
  SELECT * FROM t1 JOIN v1 ON (c1.a = v1.a);
                                QUERY PLAN
-----
Hash Join  (cost=3.27..18181.67 rows=101 width=8)
  Hash Cond: (t1.a = t2.a)
    -> Seq Scan on t1  (cost=0.00..14427.01 rows=1000101 width=4)
    -> Hash  (cost=2.01..2.01 rows=101 width=4)
        -> Seq Scan on t2  (cost=0.00..2.01 rows=101 width=4)

```

And one more example:

```

CREATE VIEW v1 AS SELECT count(*) FROM t1 WHERE f1 < 2;
/*+ IndexOnlyScan(t1) */ EXPLAIN (COSTS OFF, TIMING OFF, SUMMARY OFF)
SELECT * FROM v1;
                                QUERY PLAN
-----
Aggregate
 -> Index Only Scan using t1_idx1 on t1
     Index Cond: (f1 < 2)

```

Be careful not to select tables with identical names in different views because these tables may become affected. To avoid this, try using unique aliases, for example, a combination of a view name and a table name:

```

/*+ SeqScan(t1) */ EXPLAIN (COSTS OFF, TIMING OFF, SUMMARY OFF)
SELECT * FROM v2;
                                QUERY PLAN
-----
Nested Loop Semi Join
  Join Filter: ((count(*)) = t1.f1)
    -> Aggregate
        -> Seq Scan on t1 t1_1
            Filter: (f1 < 2)
    -> Seq Scan on t1

```

### F.41.5.7. Inheritance

Hints can point only at the parent of an inheritance tree, yet they affect all the tables in the inheritance tree. Hints pointing directly at children will not take effect.

### F.41.5.8. Hinting in Multistatements

One multistatement can have exactly one hint comment and this hint affects all individual statements in the multistatement.

### F.41.5.9. VALUES Expressions

VALUES expressions in the FROM clause are named as `*VALUES*` internally, so they are hintable if it is the only VALUES expression in a query. Two or more VALUES expressions in a query cannot be distinguished by looking at EXPLAIN, which makes the results ambiguous:

```
/*+ MergeJoin(*VALUES*_1 *VALUES*) */
EXPLAIN SELECT * FROM (VALUES (1, 1), (2, 2)) v (a, b)
JOIN (VALUES (1, 5), (2, 8), (3, 4)) w (a, c) ON v.a = w.a;
INFO:  pg_hint_plan: hint syntax error at or near "MergeJoin(*VALUES*_1 *VALUES*) "
DETAIL:  Relation name "*VALUES*" is ambiguous.
        QUERY PLAN

-----
Hash Join  (cost=0.05..0.12 rows=2 width=16)
  Hash Cond: (*VALUES*_1".column1 = "*VALUES*".column1)
    ->  Values Scan on "*VALUES*_1"  (cost=0.00..0.04 rows=3 width=8)
    ->  Hash  (cost=0.03..0.03 rows=2 width=8)
          ->  Values Scan on "*VALUES*"  (cost=0.00..0.03 rows=2 width=8)
```

## F.41.6. Subqueries

Subqueries in the following context can be hinted using the `ANY_subquery` name:

```
IN (SELECT ... {LIMIT | OFFSET ...} ...)
= ANY (SELECT ... {LIMIT | OFFSET ...} ...)
= SOME (SELECT ... {LIMIT | OFFSET ...} ...)
```

For these syntaxes, the planner internally assigns a name to the subquery when planning joins on tables including it, so join hints are applicable on such joins using the implicit name. For example:

```
/*+ HashJoin(a1 ANY_subquery) */
EXPLAIN SELECT *
FROM pgbench_accounts a1
WHERE aid IN (SELECT bid FROM pgbench_accounts a2 LIMIT 10);
        QUERY PLAN

-----
Hash Semi Join  (cost=0.49..2903.00 rows=1 width=97)
  Hash Cond: (a1.aid = a2.bid)
    ->  Seq Scan on pgbench_accounts a1  (cost=0.00..2640.00 rows=100000 width=97)
    ->  Hash  (cost=0.36..0.36 rows=10 width=4)
          ->  Limit  (cost=0.00..0.26 rows=10 width=4)
                ->  Seq Scan on pgbench_accounts a2  (cost=0.00..2640.00 rows=100000
width=4)
```

#### F.41.6.1. Using the IndexOnlyScan Hint

The index scan may be unexpectedly performed on another index when the index specified in the `IndexOnlyScan` hint cannot perform the index-only scan.

#### F.41.6.2. The NoIndexScan Hint

The `NoIndexScan` hint implies `NoIndexOnlyScan`.

### F.41.6.3. Parallel Hints and UNION

A UNION can run in parallel only when all underlying subqueries are parallel-safe. Therefore, enforcing parallel on any of the subqueries allows a parallel-executable UNION to run in parallel. Meanwhile, the Parallel hint with zero workers prevents a scan from being executed in parallel.

### F.41.6.4. Setting pg\_hint\_plan Parameters by Set Hints

pg\_hint\_plan parameters influence the behavior of the module, so some parameters do not work as expected:

- Hints to change enable\_hint, enable\_hint\_table are ignored even though they are reported as “used hints” in debug logs.
- Setting debug\_print and message\_level starts working in the middle of the query processing.

## F.41.7. Errors

pg\_hint\_plan stops parsing on any error and uses the already parsed hints. Typical errors are listed below.

### F.41.7.1. Syntax Errors

Any syntactical errors or wrong hint names are reported as syntax errors. These errors are reported in the server log with the message level, which is specified by pg\_hint\_plan.message\_level if pg\_hint\_plan.debug\_print is on or above.

### F.41.7.2. Incorrect Object Definitions

Hints with incorrect object definitions are simply ignored. This kind of error is reported as “Not Used Hint” in the server log.

### F.41.7.3. Redundant or Conflicting Hints

The last hint will take effect in case of redundant or conflicting hints. This kind of error is reported as “Duplication Hint” in the server log under the same conditions as syntax errors.

### F.41.7.4. Nested Comments

A hint comment cannot be recursive. If pg\_hint\_plan finds it, hint parsing is immediately stopped and all the hints already parsed are ignored.

## F.41.8. Functional Limitations

### F.41.8.1. Influences of Planner GUC Parameters

The planner does not try to consider the joining order for the FROM clause entries more than from\_collapse\_limit. In such cases pg\_hint\_plan cannot affect the joining order.

### F.41.8.2. Hints Trying to Enforce Non-Executable Plans

The planner selects any executable plan when the enforced plan cannot be executed.

- FULL OUTER JOIN to use nested loop.
- Use of indexes that do not have columns used in quals.
- TID scans for queries without ctid conditions.

### F.41.8.3. Queries in ECPG

ECPG removes comments from queries written as embedded SQL, so hints cannot be passed to it. The only exception is the EXECUTE command that passes the query string to the server as is. The hint table can be used in this case.

#### F.41.8.4. Query Identifiers

When `compute_query_id` is enabled, Postgres Pro generates a query ID, ignoring comments. Hence, queries with different hints, still written the same way, may compute the same query ID.

#### F.41.9. Available Hints

The available hints are listed below.

**Table F.32. Hints List**

| Group       | Format                                                                  | Description                                                                                                                                        |
|-------------|-------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| Scan method | <code>SeqScan(<i>table</i>)</code>                                      | Forces the sequential scan on a table.                                                                                                             |
|             | <code>TidScan(<i>table</i>)</code>                                      | Forces the TID scan on a table.                                                                                                                    |
|             | <code>IndexScan(<i>table</i>[ <i>index</i>...])</code>                  | Forces the index scan on a table. Restricts to specified indexes, if any.                                                                          |
|             | <code>IndexOnlyScan(<i>table</i>[ <i>index</i>...])</code>              | Forces the index-only scan on a table. Restricts to specified indexes, if any. The index scan may be used if the index-only scan is not available. |
|             | <code>BitmapScan(<i>table</i>[ <i>index</i>...])</code>                 | Forces the bitmap scan on a table. Restricts to specified indexes, if any.                                                                         |
|             | <code>IndexScanRegexp(<i>table</i>[ <i>POSIX regexp</i>...])</code>     | Forces the index scan on a table. Restricts to indexes that match the specified <a href="#">POSIX regular expression</a> .                         |
|             | <code>IndexOnlyScanRegexp(<i>table</i>[ <i>POSIX regexp</i>...])</code> | Forces the index-only scan on a table. Restricts to indexes that match the specified <a href="#">POSIX regular expression</a> .                    |
|             | <code>BitmapScanRegexp(<i>table</i>[ <i>POSIX regexp</i>...])</code>    | Forces the bitmap scan on a table. Restricts to indexes that match the specified <a href="#">POSIX regular expression</a> .                        |
|             | <code>NoSeqScan(<i>table</i>)</code>                                    | Forces the deactivation of the sequential scan on a table.                                                                                         |
|             | <code>NoTidScan(<i>table</i>)</code>                                    | Forces the deactivation of the TID scan on a table.                                                                                                |
|             | <code>NoIndexScan(<i>table</i>)</code>                                  | Forces the deactivation of the index scan and index-only scan on a table.                                                                          |
|             | <code>NoIndexOnlyScan(<i>table</i>)</code>                              | Forces the deactivation of the index-only scan on a table.                                                                                         |
|             | <code>NoBitmapScan(<i>table</i>)</code>                                 | Forces the deactivation of the bitmap scan on a table.                                                                                             |
| Join method | <code>NestLoop(<i>table table</i>[ <i>table</i>...])</code>             | Forces the nested loop for joins with specified tables.                                                                                            |
|             | <code>HashJoin(<i>table table</i>[ <i>table</i>...])</code>             | Forces the hash join for joins with specified tables.                                                                                              |

|------------------------------|-------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                              | <code>MergeJoin(table table[ table...])</code>                    | Forces the merge join for joins with specified tables.                                                                                                                                                                                                                                                                                                                                                                            |
|                              | <code>NoNestLoop(table table[ table...])</code>                   | Forces the deactivation of the nested loop for joins with specified tables.                                                                                                                                                                                                                                                                                                                                                       |
|                              | <code>NoHashJoin(table table[ table...])</code>                   | Forces the deactivation of the hash join for joins with specified tables.                                                                                                                                                                                                                                                                                                                                                         |
|                              | <code>NoMergeJoin(table table[ table...])</code>                  | Forces the deactivation of the merge join for joins with specified tables.                                                                                                                                                                                                                                                                                                                                                        |
| Join order                   | <code>Leading(table table[ table...])</code>                      | Forces the join order as specified.                                                                                                                                                                                                                                                                                                                                                                                               |
|                              | <code>Leading(&lt;join pair&gt;)</code>                           | Forces the join order and directions as specified. A join pair is a pair of tables and/or other join pairs enclosed in parentheses, which can make a nested structure.                                                                                                                                                                                                                                                            |
| Control join behavior        | <code>Memoize(table table[ table...])</code>                      | Allows the topmost join of the joins involving the specified tables to memoize the inner result. Note that it does not enforce memoizing.                                                                                                                                                                                                                                                                                         |
|                              | <code>NoMemoize(table table[ table...])</code>                    | Disallows the topmost join of the joins involving the specified tables to memoize the inner result.                                                                                                                                                                                                                                                                                                                               |
| Row number correction        | <code>Rows(table table[ table...]<br/>correction)</code>          | Corrects row number of a result of the joins with the specified tables. The available correction methods are absolute ( <code>#&lt;n&gt;</code> ), addition ( <code>+&lt;n&gt;</code> ), subtraction ( <code>-&lt;n&gt;</code> ) and multiplication ( <code>*&lt;n&gt;</code> ). <code>&lt;n&gt;</code> should be a string that <code>strtod()</code> can read.                                                                   |
| Parallel query configuration | <code>Parallel(table &lt;# of workers&gt;<br/>[soft hard])</code> | Enforces or inhibits parallel execution of the specified table. <code>&lt;# of workers&gt;</code> is the desired number of parallel workers, where zero means inhibiting parallel execution. If the third parameter is <code>soft</code> (default), it only changes <code>max_parallel_workers_per_gather</code> and leaves everything else to the planner. The <code>hard</code> value enforces the specified number of workers. |
| GUC                          | <code>Set(GUC-parameter value)</code>                             | Sets the GUC parameter to the value while the planner is running.                                                                                                                                                                                                                                                                                                                                                                 |

## F.41.10. See Also

[EXPLAIN](#), [SET](#), [Chapter 19](#), [Section 15.3](#)

## F.42. pg\_pathman

### Important

Starting from Postgres Pro 12, using `pg_pathman` is not recommended. Use vanilla declarative partitioning instead, as described in [Section 5.11](#).

The `pg_pathman` is a Postgres Pro extension that provides an optimized partitioning solution for large and distributed databases. Using `pg_pathman`, you can:

- Partition large databases without downtime.
- Speed up query execution for partitioned tables.
- Manage existing partitions and add new partitions on the fly.
- Add foreign tables as partitions.
- Join partitioned tables for read and write operations.

The extension is compatible with Postgres Pro 9.5 or higher.

### F.42.1. Installation and Setup

The `pg_pathman` extension is included into the Postgres Pro. Once you have Postgres Pro installed, complete the following steps to enable `pg_pathman`:

1. Add `pg_pathman` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'pg_pathman'
```

### Important

`pg_pathman` may have conflicts with other extensions that use the same hook functions. For example, `pg_pathman` may interfere with the `pg_stat_statements` extension as they both use `ProcessUtility_hook`. To avoid such issues, `pg_pathman` must always be the last in the list of libraries: `shared_preload_libraries = 'pg_stat_statements, pg_pathman'`

2. Restart the Postgres Pro instance for the settings to take effect.
3. Create the `pg_pathman` extension as follows:

```
CREATE SCHEMA pathman;  
GRANT USAGE ON SCHEMA pathman TO PUBLIC;  
CREATE EXTENSION pg_pathman WITH SCHEMA pathman;
```

### Important

To ensure that your calls to `pg_pathman`'s functions are always secure against `search_path`-based attacks (see [CREATE EXTENSION](#) for details), install it only into a clean schema where nobody except superusers has the `CREATE` privilege for database objects.

Once `pg_pathman` is enabled, you can start partitioning tables.

## Note

During installation, `pg_pathman` creates a few RLS policies to restrict access to its own tables. Postgres Pro core, however, does not support dump/restore of databases where extensions issuing `CREATE POLICY` statements are installed. Therefore, when restoring a dump of a database where `pg_pathman` is installed, you will get error messages such as:

```
ERROR: policy "allow_select" for table "pathman_config" already exists
```

Ignore them since they do not affect whether the data being restored is complete.

## Tip

You can also build `pg_pathman` from source code by executing the following command in the `pg_pathman` directory:

```
make install USE_PGXS=1
```

When this operation is complete, follow the steps described above to complete the setup.

In addition, do not forget to set the `PG_CONFIG` variable if you want to test `pg_pathman` on a custom build of Postgres Pro. For details, see [Building and Installing PostgreSQL Extension Modules](#).

You can toggle `pg_pathman` or its specific custom nodes on and off using GUC variables. For details, see [Section F.42.5.1](#).

If you want to permanently disable `pg_pathman` for a previously partitioned table, use the `disable_pathman_for()` function:

```
SELECT disable_pathman_for('range_rel');
```

All sections and data will remain unchanged and will be handled by the standard Postgres Pro inheritance mechanism.

### F.42.1.1. Updating `pg_pathman`

If you already have a previous version of `pg_pathman` installed, complete the following steps to upgrade to a newer version:

1. Install Postgres Pro.
2. Restart your Postgres Pro cluster.
3. If you are running a previous major version of `pg_pathman` (the second digit in the version number is different), complete the update as follows:

```
ALTER EXTENSION pg_pathman UPDATE TO version;  
SET pg_pathman.enable = t;
```

where *version* is the `pg_pathman` major version number, such as 1.5.

You can check the current `pg_pathman` version by running the `pathman_version()` function.

### F.42.2. Usage

[Choosing Partitioning Strategies](#)

[Running Non-Blocking Data Migration](#)

[Partitioning by a Single Expression](#)

## Partitioning by Composite Key

### Running Multilevel Partitioning

### Using Declarative Syntax

### Managing Partitions

As your database grows, indexing mechanisms may become inefficient and cause high latency as you run queries. To improve performance, ensure scalability, and optimize database administration processes you can use partitioning — splitting a large table into smaller pieces, with each row moved to a single partition according to the partitioning key.

Traditionally, Postgres Pro has supported partitioning via table inheritance, with each partition created as a child table with a CHECK constraint. In Postgres Pro 10, support for [declarative partitioning](#) was added, which also relies on inheritance. With these approaches, the query planner has to perform an exhaustive search and check constraints on each partition to build a query plan, which may slow down queries for tables with a large number of partitions. The `pg_pathman` extension uses an optimized planning algorithms and partitioning functions based on the internal structure of the partitioned tables, which allows to achieve better performance results. For details on `pg_pathman` implementation specifics, see [Section F.42.4](#).

#### F.42.2.1. Choosing Partitioning Strategies

The `pg_pathman` extension supports the following partitioning strategies:

- Hash — maps rows to partitions using a generic hash function. Choose this strategy if most of your queries will be of the exact-match type.
- Range — maps rows to partitions based on partitioning key ranges assigned to each partition. Choose this strategy if your database contains numeric data that you are likely to query or manage by ranges. For example, you may want to query historical data by years, or review experiment results by specific numeric ranges. To achieve performance gains, `pg_pathman` uses the binary search algorithm.

By default, `pg_pathman` migrates all data from the parent table to the newly created partitions at once (*blocking partitioning*). This approach enables you to restructure the table in a single transaction, but may cause downtime if you have a lot of data. If it is critical to avoid downtime, you can use *concurrent partitioning*. In this case, `pg_pathman` writes all the updates to the newly created partitions, but keeps the original data in the parent table until you explicitly migrate it. This enables you to partition large databases without downtime, as you can choose convenient time for migration and copy data in small batches without blocking other transactions. For details on concurrent partitioning, see [Section F.42.2.2](#).

##### F.42.2.1.1. Setting up Hash Partitioning

To perform hash partitioning with `pg_pathman`, run the `create_hash_partitions()` function:

```
create_hash_partitions(parent_relid    REGCLASS,  
                      expression      TEXT,  
                      partitions_count INTEGER,  
                      partition_data   BOOLEAN DEFAULT TRUE,  
                      partition_names  TEXT[]  DEFAULT NULL,  
                      tablespaces      TEXT[]  DEFAULT NULL)
```

The `pg_pathman` module creates the specified number of partitions based on the hash function. Optionally, you can specify partition names and tablespaces by setting `partition_names` and `tablespaces` options, respectively.

You cannot add or remove partitions after the parent table is split. If required, you can replace the specified partition with another table:

```
replace_hash_partition(old_partition    REGCLASS,
```

Additional Supplied Modules  
and Extensions Shipped in  
postgrespro-ent-14-contrib

---

|               |                     |
|---------------|---------------------|
| new_partition | REGCLASS,           |
| lock_parent   | BOOL DEFAULT TRUE); |

When set to `true`, `lock_parent` parameter will prevent any `INSERT/UPDATE/ALTER TABLE` queries to parent table.

If you omit the optional `partition_data` parameter or set it to `true`, all the data from the parent table gets migrated to partitions. The `pg_pathman` module blocks the table for other transactions until data migration completes. To avoid downtime, you can set the `partition_data` parameter to `false` and later use the `partition_table_concurrently()` function to migrate your data to partitions without blocking other queries. For details, see the [Section F.42.2.2](#).

#### F.42.2.1.2. Setting up Range Partitioning

The `pg_pathman` module provides the `create_range_partitions()` for range partitioning. This function creates partitions based on the specified interval and the initial partitioning key value. New partitions are created automatically when you insert data outside of the already covered range.

```
create_range_partitions(parent_relid REGCLASS,  
                        expression TEXT,  
                        start_value ANYELEMENT,  
                        p_interval ANYELEMENT | INTERVAL,  
                        p_count INTEGER DEFAULT NULL,  
                        partition_data BOOLEAN DEFAULT TRUE)
```

The `pg_pathman` module creates partitions based on the specified parameters. If you omit the optional `p_count` parameter, `pg_pathman` calculates the required number of partitions based on the specified start value and interval. If you insert new data outside of the existing partition range, `pg_pathman` creates new partitions automatically, keeping the specified interval. This approach ensures that all partitions are of the same size, which can improve query performance and facilitate database management.

Alternatively, you can specify an array defining the bounds of partitions to be created using the `bounds` parameter:

```
create_range_partitions(parent_relid REGCLASS,  
                        expression TEXT,  
                        bounds ANYARRAY,  
                        partition_names TEXT[] DEFAULT NULL,  
                        tablespaces TEXT[] DEFAULT NULL,  
                        partition_data BOOLEAN DEFAULT TRUE)
```

If required, you can also use [partition management functions](#) to add partitions manually. For example, if there is a gap between the created partitions, `pg_pathman` cannot fill it with a new partition in an automated mode.

By default, all the data from the parent table gets migrated to the specified number of partitions. The `pg_pathman` module blocks the table for other transactions until data migration completes. To avoid downtime, you can set the `partition_data` parameter to `false` and later use the `partition_table_concurrently()` function to migrate your data to partitions without blocking other queries. For details, see the [Section F.42.2.2](#).

#### F.42.2.2. Running Non-Blocking Data Migration

If it is critical to avoid downtime, you can perform concurrent partitioning by setting the `partition_data` parameter of the partitioning function to `false`. In this case, `pg_pathman` creates empty partitions, keeping all the original data in the parent table. At the same time, all the database updates are written to the newly created partitions. You can later migrate the original data to partitions without blocking other queries using the `partition_table_concurrently()` function:

```
partition_table_concurrently(relation REGCLASS,  
                             batch_size INTEGER DEFAULT 1000,
```

where:

- `relation` is the parent table.
- `batch_size` is the number of rows to copy from the parent table to partitions at a time. You can set this parameter to any integer value from 1 to 10000.
- `sleep_time` is the time interval between migration attempts, in seconds.

The `pg_pathman` module starts a background worker to move the data from the parent table to partitions in small batches of the specified `batch_size`. If one or more rows in the batch are locked by other queries, `pg_pathman` waits for the specified `sleep_time` and tries again, up to 60 times. You can monitor the migration process in the `pathman_concurrent_part_tasks` view that shows the number of rows migrated so far:

```
[user]postgres: select * from pathman_concurrent_part_tasks ;
userid | pid  | dbid  | relid | processed | status
-----+-----+-----+-----+-----+-----
user   | 20012 | 12413 | test  | 334000    | working
(1 row)
```

If you need to stop data migration, run the `stop_concurrent_part_task()` function at any time:

```
SELECT stop_concurrent_part_task(relation REGCLASS);
```

`pg_pathman` completes the migration of the current batch and terminates the migration process.

### Tip

When `pg_pathman` migrates all the data from the parent table, you can exclude the parent table from the query plan. See the `set_enable_parent()` function description for details.

## F.42.2.3. Partitioning by a Single Expression

For both range and hash partitioning strategies, `pg_pathman` supports partitioning by expression that returns a single scalar value. The partitioning expression can reference a table column, as well as calculate the partitioning key based on one or more column values.

### Tip

If you would like to partition a table by a tuple, see [Section F.42.2.4](#).

To partition a table by expression, use `pg_pathman` [partitioning functions](#). The partitioning expression must satisfy the following conditions:

- Expression must reference at least one column of the partitioned table.
- All referenced columns must be marked as `NOT NULL`.
- Expression cannot reference system attributes, such as `oid`, `xmin`, `xmax`, etc.
- Expression cannot include subqueries.
- All functions used by expression must be marked as `IMMUTABLE`.

As the expression can return a value of virtually any type, make sure to convert it to the type you need for partitioning.

To access a partition, you must use the exact expression used for partitioning. Otherwise, `pg_pathman` cannot optimize the query. You can view the partitioning expression for each partitioned table in the `pathman_config` table.

#### F.42.2.3.1. Examples

Suppose you have the `test` table that stores some `jsonb` data:

```
CREATE TABLE test(col jsonb NOT NULL);
INSERT INTO test
SELECT format('{"key": %s, "date": "%s", "value": "%s"}',
             i, current_date, md5(i::text))::jsonb
FROM generate_series(1, 10000 * 10) as g(i);
```

To partition this data by range of the `key` value, you need to extract this value from the `jsonb` object and convert it to a numeric type, such as `bigint`:

```
SELECT create_range_partitions('test', '(col->>'key')::bigint', 1, 10000, 10);
```

`pg_pathman` splits the parent table into ten partitions, with each partition storing 10000 rows:

```
SELECT * FROM pathman_partition_list;
parent | partition | parttype | expr | range_min | range_max
-----+-----+-----+-----+-----+-----
test   | test_1    | 2        | ((col ->> 'key')::bigint) | 1         | 10001
test   | test_2    | 2        | ((col ->> 'key')::bigint) | 10001     | 20001
test   | test_3    | 2        | ((col ->> 'key')::bigint) | 20001     | 30001
test   | test_4    | 2        | ((col ->> 'key')::bigint) | 30001     | 40001
test   | test_5    | 2        | ((col ->> 'key')::bigint) | 40001     | 50001
test   | test_6    | 2        | ((col ->> 'key')::bigint) | 50001     | 60001
test   | test_7    | 2        | ((col ->> 'key')::bigint) | 60001     | 70001
test   | test_8    | 2        | ((col ->> 'key')::bigint) | 70001     | 80001
test   | test_9    | 2        | ((col ->> 'key')::bigint) | 80001     | 90001
test   | test_10   | 2        | ((col ->> 'key')::bigint) | 90001     | 100001
(10 rows)
```

#### F.42.2.4. Partitioning by Composite Key

Using `pg_pathman`, you can also perform range partitioning by composite key. A composite key consists of two or more comma-separated values, which can be columns or expressions extracting the values from the table. The expressions defining the composite key must satisfy the conditions described in [Section F.42.2.3](#).

Although `pg_pathman` does not support automatic partition creation by composite key, you can add partitions using the `add_range_partition()` function. A typical workflow is as follows:

1. Enable automatic partition naming for your table by running the `create_naming_sequence()` function.
2. Create a composite partitioning key.
3. Register a table you are going to partition with `pg_pathman` using the `add_to_pathman_config()` function.
4. Add a partition based on the defined composite partitioning key using the `add_range_partition()` function.

##### F.42.2.4.1. Examples

Suppose you have the `test` table that stores some temporal data:

```
CREATE TABLE test (logdate date NOT NULL, comment text);
```

To partition this data by month and year, you have to create a composite key:

```
CREATE TYPE test_key AS (year float8, month float8);
```

To enable automatic partition naming, run the `create_naming_sequence()` function passing the table name as an argument:

```
SELECT create_naming_sequence('test');
```

Register the `test` table with `pg_pathman`, specifying the partitioning key you are going to use:

```
SELECT add_to_pathman_config('test',  
                             '( extract(year from logdate),  
                               extract(month from logdate) )::test_key',  
                             NULL);
```

Create a partition that includes all the data in the range of ten years, starting from January of the current year:

```
SELECT add_range_partition('test',  
                           (extract(year from current_date), 1)::test_key,  
                           (extract(year from current_date + '10 years'::interval),  
                             1)::test_key);
```

### F.42.2.5. Running Multilevel Partitioning

`pg_pathman` supports multilevel partitioning for both hash and range partitioning strategies. You can use partitioning strategies in any combination: a hash- or range-partitioned table can be further partitioned by both hash or range.

To split an existing partition into several child ones, use the regular `pg_pathman` partitioning functions as explained in [Section F.42.2.1](#), passing the name of the partition to be split as the `parent_relid` parameter. You can check the exact partition names in the [pathman\\_partition\\_list](#) view.

When opting for the range-range partitioning combination, you can either choose a different partitioning expression, or use the same expression as for the parent table. In the latter case, if the selected range is larger than that of the parent partition, only those child partitions that intersect with the parent range will be in use. Other child partitions will remain empty unless their parent is merged with an adjacent partition that covers at least a part of their range.

#### F.42.2.5.1. Examples

Suppose you have the `journal` table with some logs, which is partitioned by month:

```
-- create an empty table  
CREATE TABLE journal (  
  id      SERIAL,  
  dt      TIMESTAMP NOT NULL,  
  level   INTEGER,  
  msg     TEXT);  
  
-- generate some log data into the table  
INSERT INTO journal (dt, level, msg)  
SELECT g, random() * 6, md5(g::text)  
FROM generate_series('2015-01-01'::date, '2015-12-31'::date, '1 minute') as g;  
  
-- partition the table by range  
SELECT create_range_partitions('journal', 'dt', '2015-01-01'::date, '1  
  month'::interval);
```

If having smaller partitions makes more sense at some point, you can further split the partitions by hash or range. For example, to split the `journal_1` partition into subpartitions by day, run:

```
SELECT create_range_partitions('journal_1', 'dt', '2015-01-01'::date, '1  
  day'::interval);
```

Similarly, you can use hash partitioning to create child partitions. For example, split the `journal_2` partition into five partitions by hash using the `id` column as the partitioning key:

```
SELECT create_hash_partitions('journal_2', 'id', '5');
```

#### F.42.2.6. Using Declarative Syntax

Declarative syntax for partitioning enables you to define the partitioning strategy when creating a table, as well as partition existing tables and manage table partitions using SQL commands. Postgres Pro Enterprise offers the following implementations of declarative syntax:

- Postgres Pro core functionality, described in detail in [Section 5.11.2](#).
- `pg_pathman` implementation of declarative syntax.

Depending on the chosen implementation, the available SQL command forms will differ, as explained in [CREATE TABLE](#) and [ALTER TABLE](#) descriptions.

By default, Postgres Pro core functionality is used for declarative partitioning. To enable declarative partitioning provided by `pg_pathman`, set the [partition\\_backend](#) parameter to the `pg_pathman` value. In this case, you can use declarative range and hash partitioning strategies as explained below. For the [CREATE TABLE](#) command, you can also override the [partition\\_backend](#) setting by specifying the `USING partition_backend` clause. Do not confuse this clause with `USING method`, which cannot be used when creating partitioned tables.

When running the `CREATE TABLE` command, you can use the `PARTITION BY` clause to split the resulting table into partitions by range or hash.

To create a table partitioned by range, specify the partition names, the range of values to include into each partition and, optionally, a tablespace. For example:

```
CREATE TABLE abc(id serial NOT NULL)
PARTITION BY RANGE(id)
(
    PARTITION abc_100 VALUES LESS THAN (100) TABLESPACE ts1,
    PARTITION abc_200 VALUES LESS THAN (200) TABLESPACE ts2
);
```

When creating a table partitioned by hash, you can either specify the number of partitions to create, or the exact partitions and tablespaces. For example, to create the `abc` table with three partitions, run:

```
CREATE TABLE abc(id serial NOT NULL)
PARTITION BY HASH (id) PARTITIONS (3);
```

To define the exact partitions to create, use the following statement:

```
CREATE TABLE abc(id serial NOT NULL)
PARTITION BY HASH (id)
(
    PARTITION abc_first TABLESPACE ts1,
    PARTITION abc_second TABLESPACE ts2
);
```

To partition an already created table, you can use the `ALTER TABLE` command with the `PARTITION BY` clause. For example, to split the `abc` table into three hash partitions, run:

```
ALTER TABLE abc PARTITION BY HASH (id) PARTITIONS (3);
```

When performing range partitioning of an already created table, you have to specify the lower bound of the first partition, which must not be greater than the smallest value in the partition key column, and provide the partitioning interval that defines the range of values to include into a single partition:

```
ALTER TABLE abc PARTITION BY RANGE (id) START FROM (0) INTERVAL (2000);
```

If the table to partition contains a lot of data and it is critical to avoid downtime, consider using the optional `CONCURRENTLY` clause. In this case, `pg_pathman` first creates empty partitions, and then migrates the data in batches of 1000 rows. This clause can be used for both hash and range partitioning. For example:

```
ALTER TABLE abc PARTITION BY RANGE (id) START FROM (0) INTERVAL (50000) CONCURRENTLY;  
ALTER TABLE abc PARTITION BY HASH (id) PARTITIONS (3) CONCURRENTLY;
```

`pg_pathman` declarative syntax also supports multilevel partitioning. Once the table is partitioned, you can run the `ALTER TABLE` command with the `PARTITION BY` clause on the partition that you would like to split. Consider the following example with hash partitioning:

```
CREATE TABLE test(a int NOT NULL, b int NOT NULL)  
    PARTITION BY by hash(a) PARTITIONS (8);
```

```
ALTER TABLE test_1  
    PARTITION BY hash(b) PARTITIONS (10);
```

As a result, the `test` table is split into eight hash partitions, and its `test_1` partition is further split into ten partitions by another key.

The `ALTER TABLE` command can also be run with partition management clauses to add, remove, or modify partitions, as explained in [ALTER TABLE](#). You can perform these actions on tables partitioned with `pg_pathman` regardless of the `partition_backend` setting.

### F.42.2.7. Managing Partitions

`pg_pathman` provides multiple functions for easy partition management. For details, see [Section F.42.5.3.4](#).

## F.42.3. Examples

### F.42.3.1. Common Tips

- You can add `partition` column containing the names of the underlying partitions using the system attribute called `tableoid`:

```
SELECT tableoid::regclass AS partition, * FROM partitioned_table;
```

- Though indices on a parent table are not particularly useful (since the parent table is supposed to be empty), they act as prototypes for indices on partitions. For each index on the parent table, `pg_pathman` creates a similar index on each partition.
- All running concurrent partitioning tasks can be listed using the `pathman_concurrent_part_tasks` view:

```
SELECT * FROM pathman_concurrent_part_tasks;  
userid | pid  | dbid  | relid | processed | status  
-----+-----+-----+-----+-----+-----  
user   | 7367 | 16384 | test  | 472000    | working  
(1 row)
```

- The `pathman_partition_list` in conjunction with `drop_range_partition()` can be used to drop range partitions in a more flexible way compared to `DROP TABLE`:

```
SELECT drop_range_partition(partition, false) /* move data to parent */  
FROM pathman_partition_list  
WHERE parent = 'part_test'::regclass AND range_min::int < 500;  
NOTICE:  1 rows copied from part_test_11  
NOTICE: 100 rows copied from part_test_1  
NOTICE: 100 rows copied from part_test_2
```

```
drop_range_partition
```

```
-----
```

```
dummy_test_11  
dummy_test_1  
dummy_test_2  
(3 rows)
```

- You can turn foreign tables into partitions using the `attach_range_partition()` function. Rows that were meant to be inserted into the parent will be redirected to foreign partitions using `PartitionFilter`. By default, it is only allowed to insert rows into partitions provided by `postgres_fdw`. This setting is controlled by the `pg_pathman.insert_into_fdw` variable. You must have superuser rights to change this setting.

### F.42.3.2. Hash Partitioning

Consider an example of hash partitioning. First create a table with an integer column:

```
CREATE TABLE items (  
id          SERIAL PRIMARY KEY,  
name        TEXT,  
code        BIGINT);  
  
INSERT INTO items (id, name, code)  
SELECT g, md5(g::text), random() * 100000  
FROM generate_series(1, 100000) as g;
```

Now run the `create_hash_partitions()` function with appropriate arguments:

```
SELECT create_hash_partitions('items', 'id', 100);
```

This will create new partitions and move the data from the parent table to partitions.

Here is an example of the query performing filtering by partitioning key:

```
SELECT * FROM items WHERE id = 1234;  
 id | name | code  
----+-----+-----  
1234 | 81dc9bdb52d04dc20036dbd8313ed055 | 1855  
(1 row)
```

```
EXPLAIN SELECT * FROM items WHERE id = 1234;  
QUERY PLAN
```

```
-----  
Append  (cost=0.28..8.29 rows=0 width=0)  
->  Index Scan using items_34_pkey on items_34  (cost=0.28..8.29 rows=0 width=0)  
Index Cond: (id = 1234)
```

Notice that the `Append` node contains only one child scan, which corresponds to the `WHERE` clause.

### Important

Pay attention to the fact that `pg_pathman` excludes the parent table from the query plan.

To access the parent table, use the `ONLY` modifier:

```
EXPLAIN SELECT * FROM ONLY items;  
QUERY PLAN  
-----  
Seq Scan on items  (cost=0.00..0.00 rows=1 width=45)
```

### F.42.3.3. Range Partitioning

Consider an example of range partitioning. Let's create a table containing some dummy logs:

```
CREATE TABLE journal (  
id      SERIAL,  
dt      TIMESTAMP NOT NULL,  
level   INTEGER,  
msg     TEXT);  
  
-- similar index will also be created for each partition  
CREATE INDEX ON journal(dt);  
  
-- generate some data  
INSERT INTO journal (dt, level, msg)  
SELECT g, random() * 6, md5(g::text)  
FROM generate_series('2015-01-01'::date, '2015-12-31'::date, '1 minute') as g;
```

Run the `create_range_partitions()` function to create partitions so that each partition would contain the data for one day:

```
SELECT create_range_partitions('journal', 'dt', '2015-01-01'::date, '1 day'::interval);
```

It will create 364 partitions and move the data from the parent table to partitions.

New partitions are appended automatically by insert trigger, but it can be done manually with the following functions:

```
-- add new partition with specified range  
SELECT add_range_partition('journal', '2016-01-01'::date, '2016-01-07'::date);  
  
-- append new partition with default range  
SELECT append_range_partition('journal');
```

The first one creates a partition with specified range. The second one creates a partition with default interval and appends it to the partition list. It is also possible to attach an existing table as partition. For example, we may want to attach an archive table (or even foreign table from another server) for some outdated data:

```
CREATE FOREIGN TABLE journal_archive (  
id      INTEGER NOT NULL,  
dt      TIMESTAMP NOT NULL,  
level   INTEGER,  
msg     TEXT)  
SERVER archive_server;  
  
SELECT attach_range_partition('journal', 'journal_archive', '2014-01-01'::date,  
    '2015-01-01'::date);
```

#### **Important**

The attached table must have the same columns as the partitioned table, except for the dropped columns. The attached columns must have the same type, collation, and NOT NULL settings as the original columns.

To merge two adjacent partitions, use the `merge_range_partitions()` function:

```
SELECT merge_range_partitions('journal_archive', 'journal_1');
```

To split partition by value, use the `split_range_partition()` function:

```
SELECT split_range_partition('journal_366', '2016-01-03'::date);
```

To detach partition, use the `detach_range_partition()` function:

```
SELECT detach_range_partition('journal_archive');
```

Here is an example of the query performing filtering by partitioning key:

```
SELECT * FROM journal WHERE dt >= '2015-06-01' AND dt < '2015-06-03';
id      |          dt          | level |          msg
-----+-----+-----+-----
217441  | 2015-06-01 00:00:00 |     2 | 15053892d993ce19f580a128f87e3dbf
217442  | 2015-06-01 00:01:00 |     1 | 3a7c46f18a952d62ce5418ac2056010c
217443  | 2015-06-01 00:02:00 |     0 | 92c8de8f82faf0b139a3d99f2792311d
...
(2880 rows)

EXPLAIN SELECT * FROM journal WHERE dt >= '2015-06-01' AND dt < '2015-06-03';
QUERY PLAN
-----
Append  (cost=0.00..58.80 rows=0 width=0)
-> Seq Scan on journal_152  (cost=0.00..29.40 rows=0 width=0)
-> Seq Scan on journal_153  (cost=0.00..29.40 rows=0 width=0)
(3 rows)
```

## F.42.4. Internals

`pg_pathman` stores partitioning configuration in the `pathman_config` table; each row contains a single entry for a partitioned table (relation name, partitioning column and its type). During the initialization stage the `pg_pathman` module caches some information about child partitions in the shared memory, which is used later for plan construction. Before a `SELECT` query is executed, `pg_pathman` traverses the condition tree in search of expressions like:

```
VARIABLE OP CONST
```

where `VARIABLE` is a partitioning key, `OP` is a comparison operator (supported operators are `=`, `<`, `<=`, `>`, `>=`), `CONST` is a scalar value. For example:

```
WHERE id = 150
```

Based on the partitioning type and condition's operator, `pg_pathman` searches for the corresponding partitions and builds the plan.

### F.42.4.1. Custom Plan Nodes

`pg_pathman` provides a couple of *custom plan nodes* which aim to reduce execution time, namely:

- `RuntimeAppend` (overrides `Append` plan node)
- `RuntimeMergeAppend` (overrides `MergeAppend` plan node)
- `PartitionFilter` (drop-in replacement for `INSERT` triggers)
- `PartitionRouter` for cross-partition `UPDATE` queries instead of triggers

`PartitionFilter` acts as a *proxy node* for `INSERT`'s child scan, which means it can redirect output tuples to the corresponding partition:

```
EXPLAIN (COSTS OFF)
INSERT INTO partitioned_table
SELECT generate_series(1, 10), random();
```

QUERY PLAN

```
-----  
Insert on partitioned_table  
-> Custom Scan (PartitionFilter)  
    -> Subquery Scan on "*SELECT*"  
        -> Result  
(4 rows)
```

PartitionRouter is another proxy node used in conjunction with PartitionFilter to enable cross-partition UPDATE operations, for example, when you update any column of a partitioning key.

### Important

The PartitionRouter node transforms cross-partition UPDATE commands into DELETE + INSERT. On Postgres Pro versions prior to 11, this operation is unsafe as pg\_pathman cannot determine whether the updated row has been deleted or moved to another partition.

By default, PartitionRouter is disabled to avoid undesirable side effects. To enable this node, set the pg\_pathman.enable\_partitionrouter to on.

```
EXPLAIN (COSTS OFF)  
UPDATE partitioned_table  
SET value = value + 1 WHERE value = 2;  
QUERY PLAN
```

```
-----  
Update on partitioned_table_0  
-> Custom Scan (PartitionRouter)  
    -> Custom Scan (PartitionFilter)  
        -> Seq Scan on partitioned_table_0  
            Filter: (value = 2)  
(5 rows)
```

RuntimeAppend and RuntimeMergeAppend have much in common: they come in handy in a case when WHERE condition takes form of:

VARIABLE OP PARAM

This kind of expressions can no longer be optimized at planning time since the parameter's value is not known until the execution stage takes place. The problem can be solved by embedding the *WHERE condition analysis routine* into the original Append's code, thus making it pick only required scans out of a whole bunch of planned partition scans. This effectively boils down to creation of a custom node capable of performing such a check.

There are at least several cases that demonstrate usefulness of these nodes:

```
/* create table we're going to partition */  
CREATE TABLE partitioned_table(id INT NOT NULL, payload REAL);  
  
/* insert some data */  
INSERT INTO partitioned_table  
SELECT generate_series(1, 1000), random();  
  
/* perform partitioning */  
SELECT create_hash_partitions('partitioned_table', 'id', 100);  
  
/* create ordinary table */  
CREATE TABLE some_table AS SELECT generate_series(1, 100) AS VAL;
```

**Additional Supplied Modules  
and Extensions Shipped in  
postgrespro-ent-14-contrib**

---

- `id = (select ... limit 1)`

```
EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = (SELECT * FROM some_table LIMIT 1);
```

QUERY PLAN

```
-----
Custom Scan (RuntimeAppend) (actual time=0.030..0.033 rows=1 loops=1)
  InitPlan 1 (returns $0)
    -> Limit (actual time=0.011..0.011 rows=1 loops=1)
      -> Seq Scan on some_table (actual time=0.010..0.010 rows=1 loops=1)
    -> Seq Scan on partitioned_table_70 partitioned_table (actual time=0.004..0.006
rows=1 loops=1)
      Filter: (id = $0)
      Rows Removed by Filter: 9
Planning time: 1.131 ms
Execution time: 0.075 ms
(9 rows)
```

```
/* disable RuntimeAppend node */
SET pg_pathman.enable_runtimeappend = f;
```

```
EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = (SELECT * FROM some_table LIMIT 1);
```

QUERY PLAN

```
-----
Append (actual time=0.196..0.274 rows=1 loops=1)
  InitPlan 1 (returns $0)
    -> Limit (actual time=0.005..0.005 rows=1 loops=1)
      -> Seq Scan on some_table (actual time=0.003..0.003 rows=1 loops=1)
    -> Seq Scan on partitioned_table_0 (actual time=0.014..0.014 rows=0 loops=1)
      Filter: (id = $0)
      Rows Removed by Filter: 6
    -> Seq Scan on partitioned_table_1 (actual time=0.003..0.003 rows=0 loops=1)
      Filter: (id = $0)
      Rows Removed by Filter: 5
      ... /* more plans follow */
Planning time: 1.140 ms
Execution time: 0.855 ms
(306 rows)
```

- `id = ANY (select ...)`

```
EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = any (SELECT * FROM some_table limit 4);
```

QUERY PLAN

```
-----
Nested Loop (actual time=0.025..0.060 rows=4 loops=1)
  -> Limit (actual time=0.009..0.011 rows=4 loops=1)
    -> Seq Scan on some_table (actual time=0.008..0.010 rows=4 loops=1)
  -> Custom Scan (RuntimeAppend) (actual time=0.002..0.004 rows=1 loops=4)
    -> Seq Scan on partitioned_table_70 partitioned_table (actual
time=0.001..0.001 rows=10 loops=1)
    -> Seq Scan on partitioned_table_26 partitioned_table (actual
time=0.002..0.003 rows=9 loops=1)
    -> Seq Scan on partitioned_table_27 partitioned_table (actual
time=0.001..0.002 rows=20 loops=1)
    -> Seq Scan on partitioned_table_63 partitioned_table (actual
time=0.001..0.002 rows=9 loops=1)
Planning time: 0.771 ms
```

```
Execution time: 0.101 ms
(10 rows)
```

```
/* disable RuntimeAppend node */
```

```
SET pg_pathman.enable_runtimeappend = f;
```

```
EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
```

```
WHERE id = any (SELECT * FROM some_table limit 4);
```

```
QUERY PLAN
```

```
-----
Nested Loop Semi Join (actual time=0.531..1.526 rows=4 loops=1)
  Join Filter: (partitioned_table.id = some_table.val)
  Rows Removed by Join Filter: 3990
  -> Append (actual time=0.190..0.470 rows=1000 loops=1)
    -> Seq Scan on partitioned_table (actual time=0.187..0.187 rows=0 loops=1)
    -> Seq Scan on partitioned_table_0 (actual time=0.002..0.004 rows=6
loops=1)
    -> Seq Scan on partitioned_table_1 (actual time=0.001..0.001 rows=5
loops=1)
    -> Seq Scan on partitioned_table_2 (actual time=0.002..0.004 rows=14
loops=1)
... /* 96 scans follow */
  -> Materialize (actual time=0.000..0.000 rows=4 loops=1000)
    -> Limit (actual time=0.005..0.006 rows=4 loops=1)
      -> Seq Scan on some_table (actual time=0.003..0.004 rows=4 loops=1)
Planning time: 2.169 ms
Execution time: 2.059 ms
(110 rows)
```

- NestLoop **involving a partitioned table**, which is omitted since it's occasionally shown above.

To learn more about custom nodes, see Alexander Korotkov's [blog](#).

## F.42.5. Reference

### F.42.5.1. GUC Variables

There are several user-accessible [GUC](#) variables designed to toggle `pg_pathman` or its specific custom nodes on and off.

- `pg_pathman.enable` — enable/disable the `pg_pathman` module.

Default: on

- `pg_pathman.enable_runtimeappend` — toggle the `RuntimeAppend` custom node on/off.

Default: on

- `pg_pathman.enable_runtimemergeappend` — toggle the `RuntimeMergeAppend` custom node on/off.

Default: on

- `pg_pathman.enable_partitionfilter` — toggle the `PartitionFilter` custom node on/off to enable/disable cross-partition `INSERT` operations.

Default: on

- `pg_pathman.enable_partitionrouter` — toggle the `PartitionRouter` custom node on/off to enable/disable cross-partition `UPDATE` operations.

Default: off

- `pg_pathman.enable_auto_partition` — toggle automatic partition creation on/off (per session).

Default: on

- `pg_pathman.enable_bounds_cache` — toggle bounds cache on/off.

Default: on

- `pg_pathman.insert_into_fdw` — allow INSERT operations into various foreign-data wrappers. Possible values: disabled, postgres, and any\_fdw.

Default: postgres

- `pg_pathman.override_copy` — toggle COPY statement hooking on/off.

Default: on

## F.42.5.2. Views and Tables

### F.42.5.2.1. pathman\_config

This table stores the list of partitioned tables. This is the main configuration storage.

```
CREATE TABLE IF NOT EXISTS pathman_config (  
    partrel          REGCLASS NOT NULL PRIMARY KEY,  
    attname          TEXT NOT NULL,  
    parttype         INTEGER NOT NULL,  
    range_interval   TEXT);
```

### F.42.5.2.2. pathman\_config\_params

This table stores optional parameters that override standard `pg_pathman` behavior.

```
CREATE TABLE IF NOT EXISTS pathman_config_params (  
    partrel          REGCLASS NOT NULL PRIMARY KEY,  
    enable_parent    BOOLEAN NOT NULL DEFAULT TRUE,  
    auto             BOOLEAN NOT NULL DEFAULT TRUE,  
    init_callback    REGPROCEDURE NOT NULL DEFAULT 0,  
    spawn_using_bgw  BOOLEAN NOT NULL DEFAULT FALSE);
```

### F.42.5.2.3. pathman\_concurrent\_part\_tasks

This view lists all currently running concurrent partitioning tasks.

```
-- helper SRF function  
CREATE OR REPLACE FUNCTION show_concurrent_part_tasks()  
RETURNS TABLE (  
    userid          REGROLE,  
    pid             INT,  
    dbid            OID,  
    relid           REGCLASS,  
    processed       INT,  
    status          TEXT)  
AS 'pg_pathman', 'show_concurrent_part_tasks_internal'  
LANGUAGE C STRICT;
```

```
CREATE OR REPLACE VIEW pathman_concurrent_part_tasks  
AS SELECT * FROM show_concurrent_part_tasks();
```

### F.42.5.2.4. pathman\_partition\_list

This view lists all existing partitions, as well as their parents and range boundaries (NULL for hash partitions).

```
-- helper SRF function  
CREATE OR REPLACE FUNCTION show_partition_list()  
RETURNS TABLE (  
    parent          REGCLASS,  
    partition       REGCLASS,
```

```
parttype    INT4,
expr        TEXT,
range_min   TEXT,
range_max   TEXT)
AS 'pg_pathman', 'show_partition_list_internal'
LANGUAGE C STRICT;
```

```
CREATE OR REPLACE VIEW pathman_partition_list
AS SELECT * FROM show_partition_list();
```

## F.42.5.3. Functions

### F.42.5.3.1. Partitioning Functions

```
create_hash_partitions(parent_relid    REGCLASS,
                        expression      TEXT,
                        partitions_count INTEGER,
                        partition_data   BOOLEAN DEFAULT TRUE,
                        partition_names  TEXT[]  DEFAULT NULL,
                        tablespaces     TEXT[]  DEFAULT NULL)
```

Performs hash partitioning for relation by integer key expression. The `partitions_count` parameter specifies the number of partitions to create; it cannot be changed afterwards. If `partition_data` is `true`, all the data will be automatically migrated from the parent table to partitions. Note that data migration may take a while to finish and the table will be locked until transaction commits. See `partition_table_concurrently()` for a lock-free way to migrate data. Partition creation callback is invoked for each partition if set beforehand (see `set_init_callback()`).

```
create_range_partitions(relation      REGCLASS,
                        expression     TEXT,
                        start_value    ANYELEMENT,
                        p_interval     ANYELEMENT,
                        p_count        INTEGER DEFAULT NULL,
                        partition_data  BOOLEAN DEFAULT TRUE)
```

```
create_range_partitions(relation      REGCLASS,
                        expression     TEXT,
                        start_value    ANYELEMENT,
                        p_interval     INTERVAL,
                        p_count        INTEGER DEFAULT NULL,
                        partition_data  BOOLEAN DEFAULT TRUE)
```

```
create_range_partitions(relation      REGCLASS,
                        expression     TEXT,
                        bounds         ANYARRAY,
                        partition_names TEXT[]  DEFAULT NULL,
                        tablespaces    TEXT[]  DEFAULT NULL,
                        partition_data  BOOLEAN DEFAULT TRUE)
```

Performs range partitioning for relation by partitioning key defined by expression. The `start_value` argument specifies the initial value, `p_interval` sets the default range for automatically created partitions or partitions created with `append_range_partition()` or `prepend_range_partition()`. If `p_interval` is set to `NULL`, automatic partition creation is disabled. `p_count` is the number of premade partitions. If `p_count` is not set, than `pg_pathman` tries to determine the number of partitions based on the expression value. The `bounds` array defines the bounds for partitions to be created. You can build this array using the `generate_range_bounds()` function. Partition creation callback is invoked for each partition if set beforehand.

### F.42.5.3.2. Data Migration Functions

```
partition_table_concurrently(relation REGCLASS,
```

## Additional Supplied Modules and Extensions Shipped in

postgrespro-ent-14-contrib

```
batch_size INTEGER DEFAULT 1000,  
sleep_time FLOAT8 DEFAULT 1.0)
```

Starts a background worker to move data from parent table to partitions. The worker utilizes short transactions to copy small batches of data (up to 10K rows per transaction) and thus doesn't significantly interfere with user's activity.

```
stop_concurrent_part_task(relation REGCLASS)
```

Stops a background worker performing a concurrent partitioning task. Note: worker will exit after it finishes relocating a current batch.

### F.42.5.3.3. Triggers

Triggers are no longer required for `INSERT` and cross-partition `UPDATE` operations. However, user-supplied triggers are supported:

- Each inserted row results in execution of BEFORE/AFTER `INSERT` trigger functions of a corresponding partition.
- Each updated row results in execution of BEFORE/AFTER `UPDATE` trigger functions of a corresponding partition.
- Each moved row (cross-partition update) results in execution of BEFORE `UPDATE` + BEFORE/AFTER `DELETE` + BEFORE/AFTER `INSERT` trigger functions of corresponding partitions.

### F.42.5.3.4. Partition Management Functions

```
replace_hash_partition(old_partition    REGCLASS,  
                       new_partition    REGCLASS,  
                       lock_parent      BOOLEAN DEFAULT TRUE)
```

Replaces the specified partition of hash-partitioned table with another table. When set to `true`, the `lock_parent` parameter prevents any `INSERT/UPDATE/ALTER TABLE` queries to the parent table.

```
split_range_partition(partition_relid  REGCLASS,  
                      split_value      ANYELEMENT,  
                      partition_name    TEXT DEFAULT NULL,  
                      tablespace       TEXT DEFAULT NULL)
```

Split range partition in two by value, with the specified value included into the second partition. Partition creation callback is invoked for a new partition if available.

```
merge_range_partitions(variadic partitions REGCLASS[])
```

Merge several adjacent range partitions. Partitions are automatically ordered by increasing bounds. All the data will be accumulated in the first partition, while other merged partitions are removed. If the remaining partition has any child partitions, new child partitions for the merged data will be created as required using the same partitioning expression.

```
append_range_partition(parent_relid    REGCLASS,  
                       partition_name  TEXT DEFAULT NULL,  
                       tablespace      TEXT DEFAULT NULL)
```

Append new range partition with `pathman_config.range_interval` as interval.

```
prepend_range_partition(parent_relid    REGCLASS,  
                        partition_name  TEXT DEFAULT NULL,  
                        tablespace      TEXT DEFAULT NULL)
```

Prepend new range partition with `pathman_config.range_interval` as interval.

```
add_range_partition(parent_relid    REGCLASS,  
                    start_value     ANYELEMENT,
```

Additional Supplied Modules  
and Extensions Shipped in  
postgrespro-ent-14-contrib

---

```
end_value      ANYELEMENT,  
partition_name TEXT DEFAULT NULL,  
tablespace     TEXT DEFAULT NULL)
```

Create a new range partition for `relation` with the specified range bounds. If the `start_value` or the `end_value` is `NULL`, the corresponding range bound will be infinite.

```
drop_range_partition(partition_relid TEXT, delete_data BOOLEAN DEFAULT TRUE)
```

Drop range partition and all of its data if `delete_data` is `true`.

```
attach_range_partition(parent_relid    REGCLASS,  
                       partition_relid REGCLASS,  
                       start_value     ANYELEMENT,  
                       end_value       ANYELEMENT)
```

Attach partition to the existing range-partitioned relation. The attached table must have exactly the same structure as the parent table, including the dropped columns. Partition creation callback is invoked if `set` (see [Section F.42.5.2.2](#)).

```
detach_range_partition(partition_relid REGCLASS)
```

Detach partition from the existing range-partitioned relation.

```
disable_pathman_for(parent_relid REGCLASS)
```

Permanently disable `pg_pathman` partitioning mechanism for the specified parent table and remove the insert trigger if it exists. All partitions and data remain unchanged.

```
drop_partitions(parent_relid REGCLASS,  
                delete_data  BOOLEAN DEFAULT FALSE)
```

Drop partitions of the parent table (both foreign and local relations). If `delete_data` is `false`, the data is copied to the parent table first. Default is `false`.

#### F.42.5.3.5. Additional Functions

```
pathman_version()
```

Returns the `pg_pathman` version number.

```
set_interval(relation REGCLASS, value ANYELEMENT)
```

Update range-partitioned table interval. Note that interval must not be negative and it must not be trivial, i.e. its value should be greater than zero for numeric types, at least 1 microsecond for `timestamp` and at least 1 day for `date`.

```
set_enable_parent(relation REGCLASS, value BOOLEAN)
```

Include/exclude parent table into/from query plan. In original Postgres Pro planner parent table is always included into query plan even if it's empty, which can lead to additional overhead. You can use `disable_parent()` if you are never going to use parent table as a storage. Default value depends on the `partition_data` parameter specified during initial partitioning with the `create_range_partitions()` function. If the `partition_data` parameter was `true`, then all data have already been migrated to partitions and the parent table is disabled. Otherwise, it is enabled.

```
set_auto(relation REGCLASS, value BOOLEAN)
```

Enable/disable auto partition propagation (only for range partitioning). It is enabled by default.

```
set_init_callback(relation REGCLASS, callback REGPROCEDURE DEFAULT 0)
```

Set partition creation callback to be invoked for each attached or created partition (both hash and range). If callback is marked with `SECURITY INVOKER`, it is executed with the privileges of the user who produced a statement that has led to creation of a new partition. For example:

```
INSERT INTO partitioned_table VALUES (-5)
```

The callback must have the following signature: `part_init_callback(args JSONB) RETURNS VOID`. Parameter `arg` consists of several fields whose presence depends on partitioning type:

```
/* Range-partitioned table abc (child abc_4) */
{
    "parent":      "abc",
    "parttype":    "2",
    "partition":   "abc_4",
    "range_max":   "401",
    "range_min":   "301"
}
```

```
/* Hash-partitioned table abc (child abc_0) */
{
    "parent":      "abc",
    "parttype":    "1",
    "partition":   "abc_0"
}
```

```
set_spawn_using_bgw(relation REGCLASS, value BOOLEAN)
```

When inserting new data beyond the partitioning range, use `SpawnPartitionsWorker` to create new partitions in a separate transaction.

```
create_naming_sequence(parent_relid REGCLASS)
```

Enable automatic partition naming for the specified `relation` table. You must run this function when partitioning this table by composite key.

```
add_to_pathman_config(parent_relid    REGCLASS,
                      expression      TEXT,
                      range_interval  TEXT)
add_to_pathman_config(parent_relid    REGCLASS,
                      expression      TEXT)
```

Register the specified `relation` table with `pg_pathman` to enable partitioning by the provided `expression`. For range partitioning, the `range_interval` argument is mandatory. You can set it to `NULL` if you are going to add partition manually.

```
generate_range_bounds(p_start    ANYELEMENT,
                      p_interval INTERVAL,
                      p_count     INTEGER)
```

```
generate_range_bounds(p_start    ANYELEMENT,
                      p_interval ANYELEMENT,
                      p_count     INTEGER)
```

Build the `bounds` array that defines the bounds for partitions to be created. You can pass this array as an argument to the `create_range_partitions()` function.

## F.43. pg\_proaudit

The `pg_proaudit` extension enables detailed logging of various security events.

`pg_proaudit` works in parallel with the standard PostgreSQL logging solutions (logging collector) and does not depend on them. Security event log of the `pg_proaudit` extension is stored separately from the server log. At the Postgres Pro Enterprise startup, `pg_proaudit` launches a special background process to log security events.

Logging rules are stored in the `pg_proaudit.conf` configuration file located in the cluster data directory (PGDATA). It is a text file that can be edited directly using operating system facilities. To modify the file using SQL, you can use several `pg_proaudit` functions. The `pg_proaudit_settings` view displays the current `pg_proaudit` rules, even if they have not been saved into the `pg_proaudit.conf` file yet.

All the logged events belong to the following classes:

- DDL commands for creating, changing, and deleting DBMS objects (databases, tablespaces, schemas, tables, views, sequences, languages, functions)
- access control commands for database objects (GRANT, REVOKE)
- DML commands for access to database objects (INSERT, UPDATE, DELETE, SELECT, TRUNCATE for tables and/or views, EXECUTE for functions)
- database authentication/disconnection events
- all commands executed by a particular user

Security events can be logged both in the centralized logging solution of the operating system (syslog) and in the standard file-system files. Event logs can be written both into the syslog and into the files simultaneously. For clear identification, all `pg_proaudit` records in the syslog are marked with `AUDIT`. Event log files can be written in the CEF (Common Event Format) and CSV (Comma-Separated Values) formats. Each event is logged on a separate line that contains the following fields:

- date and time of the event
- current user name
- database name
- server process ID (PID)
- severity level: `INFO` or `ERROR`
- serial number of the command in a session
- subcommand number in complex commands (CREATE TABLE ... AS SELECT ...)
- operator name
- object type
- object name
- operator execution results: `SUCCESS` or `FAILURE`
- additional information like error message in case of `FAILURE` or connection parameters and the application name for the `AUTHENTICATE` event; unfinished authentication attempts are marked as [EOF. No credentials provided]
- text of the SQL command
- parameters of the command (for example, for `PREPARE`)
- session user name
- unique ID of the event (in the [UUIDv7](#) format)
- transaction ID (XID)
- virtual transaction ID (VXID)

An event contains the information about both `session_user` and `current_user` of the session. Therefore, it will be possible to identify the user, even if they execute the `SET ROLE` command to change user identifier.

The XID and VXID values can be zero if an event does not relate to a transaction (e. g. the `DISCONNECT` event).

You can define a directory to store security log files and set up log file rotation. `pg_proaudit` can switch to a new log file either after the specified time interval, or when the specified size of the log file is exceeded. This enables you to define a workflow for cleaning up security event logs.

Postgres Pro user with the `SUPERUSER` attribute should grant access to the `pg_proaudit` extension and security event log files only to the user with the information security administrator role.

### F.43.1. Installing the `pg_proaudit` Extension

The `pg_proaudit` extension is a built-in extension included into Postgres Pro Enterprise. To enable `pg_proaudit`, complete the following steps:

1. Add `pg_proaudit` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'pg_proaudit'
```

2. Restart the database server for the changes to take effect. To verify that the `pg_proaudit` library was installed correctly, you can run the following command:

```
SHOW shared_preload_libraries;
```

3. In each database for which you are going to log security events, create the `pg_proaudit` extension using the following query:

```
CREATE EXTENSION pg_proaudit;
```

The `pg_proaudit` extension adds several functions for managing the `pg_proaudit.conf` file, the `pg_proaudit_settings` view that displays the current `pg_proaudit` rules and event triggers.

### F.43.2. Uninstalling the `pg_proaudit` Extension

To properly uninstall `pg_proaudit`, complete the following steps:

1. Delete the `pg_proaudit` extension using the following query:

```
DROP EXTENSION pg_proaudit;
```

2. Remove `pg_proaudit` from the `shared_preload_libraries` variable in the `postgresql.conf` file.

Skip this step if you have several databases in the cluster and you want to remove the extension only for one of them. In this case, it is recommended to remove logging rules related to the corresponding database prior to uninstalling the extension.

### F.43.3. Functions to Configure Security Event Logging

To configure security event logging, `pg_proaudit` provides an SQL interface that consists of several functions and the `pg_proaudit_settings` view.

```
pg_proaudit_set_rule(db_name text, event_type text, object_type text, object_name text,  
                    role_name text, comment text)
```

Creates the logging rule with the specified parameters. When the `pg_proaudit_set_rule()` function completes, security event logging starts immediately, but the `pg_proaudit.conf` file is not updated. To save the changes in the `pg_proaudit.conf` file, call the `pg_proaudit_save()` function.

Arguments:

- `db_name` — name of the database for which the logging rule is established. An empty string or `NULL` specified in this argument means that events are logged for all databases where the `pg_proaudit` extension is created. When set to `current_database()`, events for the current database are logged.
- `event_type` — type of the event that needs to be logged, including SQL operator names, as well as `AUTHENTICATE` and `DISCONNECT` events. When set to `ALL`, as well as when an empty string or

NULL is specified, enables logging for all events available for the specified object type. For example, for the TABLE object type, the ALL keyword enables logging for commands SELECT, INSERT, UPDATE, DELETE, TRUNCATE, COPY, as well as CREATE, ALTER, DROP. You can also set up logging of event classes by specifying the following values: ALL\_DDL, ALL\_DDL\_NONTEMP, ALL\_DML, ALL\_DML\_NONTEMP, ALL\_MOD, ALL\_PROC, ALL\_ROLE, and MISC. For the full list of possible *event\_type* values, see [Section F.43.5](#).

- *object\_type* — type of the object for which security events need to be logged. When set to ALL, as well as when an empty string or the NULL is specified, enables logging of events for all object types. For example, specify FOREIGN TABLE object type for the SELECT event to log all attempts to access foreign tables. Use NULL if *event\_type* is set to AUTHENTICATE, DISCONNECT, SET, or RESET, and the ROLE value for all events that reference user actions, such as CREATE USER or DROP USER. The following object types are supported: COMPOSITE TYPE, DATABASE, EVENT TRIGGER, FUNCTION, INDEX, PREPARED STATEMENT, ROLE, SEQUENCE, SCHEMA, TABLE, FOREIGN TABLE, TOAST TABLE, TABLESPACE, VIEW, MATERIALIZED VIEW, CATALOG RELATION, and CATALOG FUNCTION.

### Note

To log security events for system catalog objects, it is required to enable the [pg\\_proaudit.log\\_catalog\\_access](#) configuration parameter. Otherwise, these events will not be logged, even if the CATALOG RELATION, CATALOG FUNCTION, or ALL object type is specified in the rule.

- *object\_name* — name of the object for which the logging rule is established. When an empty string or NULL is specified, enables logging of events for all object names.
- *role\_name* — name of the role for which the logging rule is established. If specified, allows logging the actions caused by the user who has the privileges of the role. This means that at least one of the user session attributes, *session\_user* or *current\_user*, should either be equal to the *role\_name*, or be directly or indirectly a member of this role. When an empty string or NULL is specified, enables logging of actions caused by any user. When set to [current\\_role](#), the logging rule is established for the user current role.
- *comment* — comment to describe the created logging rule. This argument does not affect the rule execution and is not reflected in the log.

```
pg_proaudit_remove_rule(db_name text, event_type text, object_type text, object_name  
text, role_name text)
```

Removes the specific logging rule with the set parameters. To save the changes in the `pg_proaudit.conf` file, call the `pg_proaudit_save()` function.

### Note

If the rule that you want to remove is configured to log the DISCONNECT event type, then disconnect events may still be logged after the rule is removed. For additional information, see [Section F.43.3.1](#).

#### Arguments:

- *db\_name* — name of the database for which the logging rule needs to be removed.
- *event\_type* — type of the event for which the logging rule needs to be removed. For the full list of possible *event\_type* values, see [Section F.43.5](#).
- *object\_type* — type of the object for which the logging rule needs to be removed.
- *object\_name* — name of the object for which the logging rule needs to be removed.
- *role\_name* — name of the role for which the logging rule needs to be removed.

```
pg_proaudit_show()
```

Returns logged events in a table view. This function is used by the `pg_proaudit_settings` view.

```
pg_proaudit_reload()
```

Reads logging configuration from the `pg_proaudit.conf` file. You must call this function if the `pg_proaudit.conf` file was modified manually using the operating system facilities.

```
pg_proaudit_reset()
```

Removes all logging rules. To save information about the canceled logging in the `pg_proaudit.conf` file, call the `pg_proaudit_save()` function.

```
pg_proaudit_save()
```

Saves logging rules from memory into the `pg_proaudit.conf` file. The `pg_proaudit.conf` file is located in the cluster data directory (PGDATA). You cannot change the `pg_proaudit.conf` file location.

### F.43.3.1. Handling Database Disconnection Events

When a logging rule is configured for `DISCONNECT` event type, and a user authenticates in a database, then the `pg_proaudit` extension checks whether the corresponding disconnection event satisfies the rule and must be logged.

If the event must be logged, then the removal of the logging rule has no effect on the event. This event will be logged no matter if the logging rule exists at the moment of disconnect.

Consider the following example:

1. An administrator configures the following logging rule:

```
SELECT pg_proaudit_set_rule ('postgres', 'DISCONNECT', null, null, null, 'Any  
disconnect from the postgres DB');
```

2. A user connects to the `postgres` database and goes through authentication.

For the rule in effect, a corresponding disconnection event will be logged later.

3. The administrator removes the logging rule, while the user is still connected to the database:

```
SELECT pg_proaudit_remove_rule('postgres', 'DISCONNECT', null, null, null);
```

4. The user disconnects from the database.

The corresponding disconnection event is logged despite the removal of the logging rule.

### F.43.3.2. Handling Object Names

Comparison of string representations of names for database, user, role and other objects is case-insensitive even if the object name in the database is enclosed in quotes. These string representations are stored as lower-case strings.

Strings representing object names need to be passed to functions `pg_proaudit_set_rule` and `pg_proaudit_remove_rule` as regular strings: a single quote needs repeating, and other characters are passed as is, without escaping or wrapping.

For example, rules for tables `table1` and `"TaBlE1"` will be the same, and their names can be passed in upper-case or lower-case characters. The same holds for roles. As for databases, before creating a rule, `pg_proaudit` checks whether this database actually exists, and this check is case-sensitive.

The following examples illustrate creation of "weird" object names and specifying correct audit rules for them.

```
create table "TabLe'"123"();  
SELECT pg_proaudit_set_rule(current_database(), null, null, 'public.TabLe'"'"'123',  
    null, 'tst cmnt');  
create table "taBlE""123"();
```

```
SELECT pg_proaudit_set_rule(null, null, null, 'public.tablE"123', null);

create schema "(BIG!) Schema";
create table "(BIG!) Schema"."My Tab.lE"();
SELECT pg_proaudit_set_rule(null, null, null, '(BIG!) Schema.My Tab.lE', null);

create role "Some '@#$$' person" with login;
SELECT pg_proaudit_set_rule(null, 'authenticate', null, null, 'Some '@#$$' person');

create role "Some '@#$$' person" with superuser;
\c - "Some '@#$$' person"
SELECT pg_proaudit_set_rule(null, 'disconnect', null, null, current_user);

create database " D B 1";
SELECT pg_proaudit_set_rule(' D B 1', 'authenticate', null, null, null);

create database " D b 2";
\c " D b 2"
create extension pg_proaudit;
SELECT pg_proaudit_set_rule(current_database(), 'disconnect', null, null, null);
```

## F.43.4. pg\_proaudit\_settings View

This view displays the current `pg_proaudit` rules, even if they have not been saved into the `pg_proaudit.conf` file yet. The `pg_proaudit_settings` view consists of the following columns:

- `db_name` (text) — name of the database for which to log security events.
- `event_type` (text) — event type to log.
- `object_type` (text) — type of the object for which security events are to be logged.
- `object_name` (text) — name of the object for which security events are to be logged.
- `role_name` (text) — the role on behalf of which logged actions are performed.
- `comment` (text) — comment to describe the created logging rule.

## F.43.5. Security Events

You can configure the `pg_proaudit` extension to log classes of security events and specific events by specifying the respective value in the `event_type` argument of the `pg_proaudit_set_rule()` function.

The following classes of security events are supported:

- `ALL_DDL`: CREATE, ALTER, DROP for any database object except stored procedures and functions.
- `ALL_DDL_NONTEMP`: same as `ALL_DDL` but the scope is limited to the objects that are not contained in `pg_temp_nnn` temporary schemas.
- `ALL_DML`: SELECT, INSERT, UPDATE, DELETE, TRUNCATE for any table type; EXECUTE for functions and stored procedures.
- `ALL_DML_NONTEMP`: same as `ALL_DML` but the scope is limited to the objects that are not contained in `pg_temp_nnn` temporary schemas.
- `ALL_MOD`: INSERT, UPDATE, DELETE, TRUNCATE for any table type.
- `ALL_PROC`: CREATE, ALTER, DROP for any function and stored procedure.
- `ALL_ROLE`: CREATE, ALTER, DROP for USER, ROLE, GROUP, PROFILE, as well as execution of the GRANT command.
- `MISC`: all events not related to any of the other classes mentioned above.

The following specific security events are supported:

- ANALYZE
- AUTHENTICATE
- DISCONNECT
- ALTER AGGREGATE
- ALTER COLLATION
- ALTER CONVERSION

- ALTER DATABASE
- ALTER DEFAULT PRIVILEGES
- ALTER DOMAIN
- ALTER EVENT TRIGGER
- ALTER EXTENSION
- ALTER FOREIGN DATA WRAPPER
- ALTER FOREIGN TABLE
- ALTER FUNCTION
- ALTER INDEX
- ALTER LANGUAGE
- ALTER LARGE OBJECT
- ALTER MATERIALIZED VIEW
- ALTER OPERATOR
- ALTER OPERATOR CLASS
- ALTER OPERATOR FAMILY
- ALTER POLICY
- ALTER PROFILE
- ALTER ROLE, ALTER USER, ALTER GROUP
- ALTER RULE
- ALTER SCHEMA
- ALTER SEQUENCE
- ALTER SERVER
- ALTER SYSTEM
- ALTER TABLE
- ALTER TABLESPACE
- ALTER TEXT SEARCH CONFIGURATION
- ALTER TEXT SEARCH DICTIONARY
- ALTER TEXT SEARCH PARSER
- ALTER TEXT SEARCH TEMPLATE
- ALTER TRIGGER
- ALTER TYPE
- ALTER USER MAPPING
- ALTER VIEW
- CHECKPOINT
- CLUSTER
- COMMENT
- COPY
- CREATE ACCESS METHOD
- CREATE AGGREGATE
- CREATE CAST
- CREATE COLLATION
- CREATE CONVERSION
- CREATE DATABASE
- CREATE DOMAIN
- CREATE EVENT TRIGGER
- CREATE EXTENSION
- CREATE FOREIGN DATA WRAPPER
- CREATE FOREIGN TABLE
- CREATE FUNCTION
- CREATE INDEX
- CREATE LANGUAGE
- CREATE MATERIALIZED VIEW
- CREATE OPERATOR
- CREATE OPERATOR CLASS
- CREATE OPERATOR FAMILY

- CREATE POLICY
- CREATE PROFILE
- CREATE ROLE, CREATE USER, CREATE GROUP
- CREATE RULE
- CREATE SCHEMA
- CREATE SEQUENCE
- CREATE SERVER
- CREATE TABLE, CREATE TABLE AS, SELECT INTO
- CREATE TABLESPACE
- CREATE TEXT SEARCH CONFIGURATION
- CREATE TEXT SEARCH DICTIONARY
- CREATE TEXT SEARCH PARSER
- CREATE TEXT SEARCH TEMPLATE
- CREATE TRANSFORM
- CREATE TRIGGER
- CREATE TYPE
- CREATE USER MAPPING
- CREATE VIEW
- DEALLOCATE
- DELETE
- DISCARD ALL
- DISCARD PLANS
- DISCARD SEQUENCES
- DISCARD TEMP
- DO
- DROP ACCESS METHOD
- DROP AGGREGATE
- DROP CAST
- DROP COLLATION
- DROP CONVERSION
- DROP DATABASE
- DROP DOMAIN
- DROP EVENT TRIGGER
- DROP EXTENSION
- DROP FOREIGN DATA WRAPPER
- DROP FOREIGN TABLE
- DROP FUNCTION
- DROP INDEX
- DROP LANGUAGE
- DROP MATERIALIZED VIEW
- DROP OPERATOR
- DROP OPERATOR CLASS
- DROP OPERATOR FAMILY
- DROP OWNED
- DROP POLICY
- DROP PROFILE
- DROP ROLE, DROP USER, DROP GROUP
- DROP RULE
- DROP SCHEMA
- DROP SEQUENCE
- DROP SERVER
- DROP TABLE
- DROP TABLESPACE
- DROP TEXT SEARCH CONFIGURATION
- DROP TEXT SEARCH DICTIONARY

- DROP TEXT SEARCH PARSER
- DROP TEXT SEARCH TEMPLATE
- DROP TRANSFORM
- DROP TRIGGER
- DROP TYPE
- DROP USER MAPPING
- DROP VIEW
- EXECUTE
- FETCH
- GRANT
- INSERT
- MOVE
- PREPARE
- REASSIGN OWNED
- REFRESH MATERIALIZED VIEW
- REINDEX
- RESET
- REVOKE
- SECURITY LABEL
- SELECT
- SET
- UPDATE
- TRUNCATE TABLE
- VACUUM

## F.43.6. Security Event Log Configuration Parameters

The `pg_proaudit` extension provides several configuration parameters for managing security event log files. These parameters can be set in the `postgresql.conf` configuration file, or with the help of the `ALTER SYSTEM` command. For the changes to take effect, call the `pg_reload_conf()` function or restart the database server. For additional configuration, the [syslog\\_ident](#) and [syslog\\_facility](#) configuration parameters can be used.

`pg_proaudit.log_destination (string)`

Defines the method for logging security events. Possible values are:

- `csvlog` — log security events in a CSV file.
- `ceflog` — log security events in a CEF file. CEF is an open text-based format designed for log records. It contains a standard header and a variable extension formatted as key-value pairs.
- `syslog` — log security events in syslog.
- `cefsyslog` — log security events in the CEF format in syslog.

You can specify one or more values separated by commas. Note, however, that `syslog` and `cefsyslog` are mutually exclusive. If both are specified, `cefsyslog` takes precedence and `syslog` is ignored.

Default: `csvlog`

`pg_proaudit.log_catalog_access (boolean)`

Specifies whether to log access to system catalog objects in the `pg_catalog` schema.

When set to `off`, no events will be logged, even if there are rules for the `CATALOG RELATION`, `CATALOG FUNCTION`, or `ALL` object types.

It is not recommended to set the parameter to `on`, if you do not plan to log events for system catalog objects. Doing otherwise may impact Postgres Pro performance, even if there are no rules for the aforementioned object types.

Default: off

`pg_proaudit.log_command_text` (boolean)

Specifies whether to log the SQL command text for security events.

Default: on

`pg_proaudit.log_directory` (string)

Specifies the path to the directory that stores CSV and CEF log files. This can be an absolute path or a relative path to the cluster data directory (PGDATA). This parameter is used if the `csvlog` or `ceflog` value is specified in the [pg\\_proaudit.log\\_destination](#) parameter.

Default: `pg_proaudit`

`pg_proaudit.log_filename` (string)

Defines the filenames of the created security event log files. The filename template can contain %-escapes, similar to the ones listed in the `strftime` specification of the Open Group (<http://pubs.opengroup.org/onlinepubs/009695399/functions/strftime.html>). This parameter is used if the `csvlog` or `ceflog` value is specified in the [pg\\_proaudit.log\\_destination](#) parameter.

Default: `postgresql-%Y-%m-%d_%H%M%S.log`

`pg_proaudit.log_rotation_size` (integer)

Sets the maximum size of a log file, in kilobytes. When this size is achieved, `pg_proaudit` creates a new file for logging security events. If set to 0, disables size-based creation of new log files. This parameter is used if the `csvlog` or `ceflog` value is specified in the [pg\\_proaudit.log\\_destination](#) parameter.

Default: 10MB

`pg_proaudit.log_rotation_age` (integer)

Sets the maximum lifetime of a log file, in minutes. After this timeframe is elapsed, `pg_proaudit` creates a new file for logging security events. If set to 0, disables time-based creation of new log files. This parameter is used if the `csvlog` or `ceflog` value is specified in the [pg\\_proaudit.log\\_destination](#) parameter.

Default: 1 day

`pg_proaudit.log_truncate_on_rotation` (boolean)

Specifies whether to truncate log files when logging is switched to an existing log file. If set to `off`, `pg_proaudit` appends new log entries to the end of the file. This parameter is used if the `csvlog` or `ceflog` value is specified in the [pg\\_proaudit.log\\_destination](#) parameter.

Default: off

`pg_proaudit.max_rules_count` (integer)

Specifies the maximum number of rules allowed. For the parameter changes to take effect, the database server must be restarted.

Default: 500

## F.43.7. Viewing Security Event Log

Security event log files are text files that can be viewed by the operating system facilities. To access log files using SQL, you can use the `file_fdw` extension — a foreign data wrapper for accessing files on the database server. To use this method, complete the following steps:

1. Install the `file_fdw` and create an external server:

```
CREATE EXTENSION file_fdw;
CREATE SERVER pg_proauditlog FOREIGN DATA WRAPPER file_fdw;
```

2. Create a foreign table, specifying the columns and the absolute path to the log file. The actual log file location is determined by the `pg_proaudit.log_directory` and `pg_proaudit.log_filename` parameters.

```
CREATE FOREIGN TABLE pg_proaudit_log
( log_time timestamp(3) with time zone,
  current_usr_name text,
  database_name text,
  session_pid text,
  error_severity text,
  session_line_num bigint,
  session_line_subcommand_num bigint,
  event_type text,
  object_type text,
  object_name text,
  status text,
  error_message text,
  query_text text,
  query_args text,
  session_usr_name text,
  uuid text,
  xid text,
  vxid text )
```

```
SERVER pg_proauditlog
OPTIONS (filename 'absolute_file_path_to_log_file.csv', FORMAT 'csv' );
```

Make sure that the `pg_proaudit.log_destination` parameter contains the `csvlog` value, which enables writing security event logs to CSV files.

## F.43.8. Examples

As an example, let's set up logging for the following security events:

- authentications/disconnections to the `postgres` database
- all actions of the user if at least one of the user session attributes, `session_user` or `current_user`, is either explicitly set to the `postgres` role, or is directly or indirectly a member of this role
- creating, updating, and deleting any tables
- all operations on the `app_table` table that belongs to the `public` schema

All events must be logged in the CSV format and stored for a week. It is required to set up SQL access to the security event log. To complete the scenario, do the following:

In `psql`, check that the preliminary setup of the `pg_proaudit` extension is complete in the `postgres` database:

```
SHOW shared_preload_libraries;
shared_preload_libraries
```

```
-----
pg_proaudit
```

```
\dx pg_proaudit
```

List of installed extensions

| Name        | Version | Schema | Description                     |
|-------------|---------|--------|---------------------------------|
| pg_proaudit | 2.0     | public | provides auditing functionality |

Add the following lines to the `postgresql.conf` configuration file:

```
pg_proaudit.log_destination = 'csvlog'
pg_proaudit.log_directory = 'audit'
pg_proaudit.log_filename = 'audit-%u.csv'
pg_proaudit.log_rotation_age = 1440
pg_proaudit.log_rotation_size = 0
pg_proaudit.log_truncate_on_rotation = on
pg_proaudit.log_command_text = on
```

For the changes to take effect, run the following query:

```
SELECT pg_reload_conf();
```

Check that the following parameters are set as expected:

```
SHOW pg_proaudit.log_destination;
SHOW pg_proaudit.log_directory;
SHOW pg_proaudit.log_filename;
SHOW pg_proaudit.log_rotation_age;
SHOW pg_proaudit.log_rotation_size;
SHOW pg_proaudit.log_truncate_on_rotation;
SHOW pg_proaudit.log_command_text;
```

Suppose your `PGDATA` environment variable points to the cluster data directory. Since the `pg_proaudit.log_directory` defines a relative path to the log files, they will be located in the `$PGDATA/audit` directory. Let's create an empty file for each day of the week and make them available to their owner only:

```
touch $PGDATA/audit/audit-1.csv
touch $PGDATA/audit/audit-2.csv
touch $PGDATA/audit/audit-3.csv
touch $PGDATA/audit/audit-4.csv
touch $PGDATA/audit/audit-5.csv
touch $PGDATA/audit/audit-6.csv
touch $PGDATA/audit/audit-7.csv
chmod 600 $PGDATA/audit/audit-*.csv
```

Create a table for reading log entries:

```
CREATE TABLE pg_proaudit_log (
    log_time timestamp(3) with time zone,
    current_usr_name text,
    database_name text,
    session_pid text,
    error_severity text,
    session_line_num bigint,
    session_line_subcommand_num bigint,
    event_type text,
    object_type text,
    object_name text,
    status text,
    error_message text,
    query_text text,
    query_args text,
    session_usr_name text,
    uuid text,
    xid text,
    vxid text
);
```

Install the `file_fdw` extension and create an external server:

**Additional Supplied Modules  
and Extensions Shipped in  
postgrespro-ent-14-contrib**

---

```
CREATE EXTENSION file_fdw;  
CREATE SERVER pg_proauditlog FOREIGN DATA WRAPPER file_fdw;
```

**Now let's create seven child foreign tables for the pg\_proaudit\_log table, for each day of the week:**

```
CREATE FOREIGN TABLE pg_proaudit_log_1 () INHERITS (pg_proaudit_log) SERVER  
pg_proauditlog  
  OPTIONS (filename '/path_to_PGDATA/audit/audit-1.csv', FORMAT 'csv');  
CREATE FOREIGN TABLE pg_proaudit_log_2 () INHERITS (pg_proaudit_log) SERVER  
pg_proauditlog  
  OPTIONS (filename '/path_to_PGDATA/audit/audit-2.csv', FORMAT 'csv');  
CREATE FOREIGN TABLE pg_proaudit_log_3 () INHERITS (pg_proaudit_log) SERVER  
pg_proauditlog  
  OPTIONS (filename '/path_to_PGDATA/audit/audit-3.csv', FORMAT 'csv');  
CREATE FOREIGN TABLE pg_proaudit_log_4 () INHERITS (pg_proaudit_log) SERVER  
pg_proauditlog  
  OPTIONS (filename '/path_to_PGDATA/audit/audit-4.csv', FORMAT 'csv');  
CREATE FOREIGN TABLE pg_proaudit_log_5 () INHERITS (pg_proaudit_log) SERVER  
pg_proauditlog  
  OPTIONS (filename '/path_to_PGDATA/audit/audit-5.csv', FORMAT 'csv');  
CREATE FOREIGN TABLE pg_proaudit_log_6 () INHERITS (pg_proaudit_log) SERVER  
pg_proauditlog  
  OPTIONS (filename '/path_to_PGDATA/audit/audit-6.csv', FORMAT 'csv');  
CREATE FOREIGN TABLE pg_proaudit_log_7 () INHERITS (pg_proaudit_log) SERVER  
pg_proauditlog  
  OPTIONS (filename '/path_to_PGDATA/audit/audit-7.csv', FORMAT 'csv');
```

**To set up logging for the required security events, connect to the postgres database and execute the following commands:**

```
SELECT pg_proaudit_set_rule (current_database(), 'AUTHENTICATE', null, null, null, 'Any  
authentication in the current DB');  
SELECT pg_proaudit_set_rule (current_database(), 'DISCONNECT', null, null, null, 'Any  
disconnect from the current DB');  
SELECT pg_proaudit_set_rule (current_database(), 'ALL', 'TABLE', null, null, 'Any  
operations with any table in the current DB');  
SELECT pg_proaudit_set_rule (current_database(), 'ALL', null, null, 'postgres', 'Any  
operation by "postgres" user in the current DB');
```

**Create the app\_table table and enable logging for all operations on this table:**

```
CREATE TABLE app_table (id int, name text);  
SELECT pg_proaudit_set_rule (current_database(), 'ALL', null, 'public.app_table',  
null);
```

**Check that event logging is configured as expected:**

```
SELECT * FROM pg_proaudit_settings;  
db_name | event_type | object_type | object_name | role_name |  
comment  
-----+-----+-----+-----+-----+  
+-----+  
postgres | authenticate | ALL | | | Any  
authentication in the current DB  
postgres | disconnect | ALL | | | Any disconnect  
from the current DB  
postgres | ALL | table | | | Any operations  
with any table in the current DB  
postgres | ALL | ALL | | postgres | Any operation  
by "postgres" user in the current DB  
postgres | ALL | ALL | public.app_table | |
```

(5 rows)

Save these logging rules into the `pg_proaudit.conf` file, so that they are not lost after the server restart:

```
SELECT pg_proaudit_save();
```

Let's run several queries on the `app_table` table:

```
INSERT INTO app_table VALUES (1, 'first');
SELECT * FROM app_table;
```

Check the log entries for the `app_table` table:

```
SELECT to_char(log_time, 'DD.MM.YY HH24:MI:SS') AS when, current_usr_name,
       session_pid, event_type, query_text, session_usr_name
FROM pg_proaudit_log
WHERE object_name = 'public.app_table';
       when          | current_usr_name | session_pid | event_type |
query_text          | session_usr_name
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
27.09.23 12:44:27 | postgres        | 2010        | CREATE TABLE | CREATE TABLE
app_table (id int, name text); | postgres
27.09.23 12:45:55 | postgres        | 2010        | INSERT        | INSERT INTO
app_table VALUES (1, 'first'); | postgres
27.09.23 12:46:00 | postgres        | 2010        | SELECT        | SELECT * FROM
app_table;          | postgres
(3 rows)
```

We have set up a weekly rotation of log files, with the log file switched once a day. It means that queries to the `pg_proaudit_log` table will return only those security events that have happened in the latest week. Older events will be automatically removed at log file rotation. To define additional access constraints for specific log entries, you can create separate views based on queries to the `pg_proaudit_log` table and grant read rights to such views using built-in Postgres Pro access control methods.

## F.44. pgpro\_bindump

`pgpro_bindump` is a plugin designed to implement additional commands for the Postgres Pro replication protocol, specifically for use with the [pg\\_probackup3](#) utility. `pgpro_bindump` offers the following benefits:

- Simplified communication: `pgpro_bindump` does not require the SSH protocol and associated configurations to connect to a database server.
- Integrated WAL transfer: WAL files are transferred together with data files, reducing the risk of data loss during backups.
- Optimized storage: Files are not copied as they are, but are archived using the `pg_probackup3` own format, CBOR (RFC 8949 Concise Binary Object Representation), which enhances the storage efficiency.

### F.44.1. Architecture

Here are some key points of how `pgpro_bindump` works:

- A dedicated backend process is created to handle connections from external applications. You can use the `pg_probackup3` utility or a custom application to send requests to this backend.
- Multiple connections can be established for the same application if needed.
- Since the `pgpro_bindump` plugin has direct access to the database files, it does not require any additional permissions.

- `pgpro_bindump` uses the `libpgprobackup` library, along with its built-in encoder module, to send data to the application.
- The `walsender_plugin_libraries` configuration parameter simplifies the process of adding and utilizing new replication commands, including custom ones.

## F.44.2. Limitations and Requirements

`pgpro_bindump` currently has the following limitations and requirements:

- `libpgprobackup.so` and `libpb3_encoder.so` are required for `pgpro_bindump` operation.

## F.44.3. Installation and Setup

The `pgpro_bindump` plugin is included in Postgres Pro as part of the `postgrespro-ent-14-contrib` package (for the installation instructions, see [Chapter 17](#)). Once you complete Postgres Pro installation, follow the steps below.

1. Specify the following parameters in the `postgresql.conf` file:

```
shared_preload_libraries = 'pgpro_bindump'  
wal_level = 'replica' # or 'logical'  
walsender_plugin_libraries = 'pgpro_bindump'
```

2. Restart the Postgres Pro instance.

### Note

Since `pgpro_bindump` is a plugin and not an extension, the `CREATE EXTENSION` command is not needed.

## F.44.4. Replication Commands

The `pgpro_bindump` plugin implements the following replication commands:

- `just-noop` — a do-nothing command.
- `start_backup` — starts the backup process.
- `copy_files` — copies files in the CBOR format.
- `stop_backup` — stops the backup process.

The backup process runs in the *PRO mode* — an advanced backup data source mode that incorporates all available optimizations and enhancements, including the proprietary replication protocol and specialized replication commands.

To send commands from a user application to `pgpro_bindump` and to receive the output data from `pgpro_bindump` by the application, use `libpq`.

### Note

An established connection to a running Postgres Pro server is required.

### F.44.4.1. start\_backup

```
start_backup LABEL label, INCR_MODE incr_mode, START_LSN start_lsn,  
TRANSFER_MODE transfer_mode,
```

`[TRANSFER_BUFFER_SIZE buffer_size]`

Starts the backup process. Sends the following data to the application:

- `start_lsn` — LSN at the start of the backup.
- `start_tli` — the timeline ID at the start of the backup.
- `min_xid` — the minimal transaction ID at the start of the backup.
- `min_multixact` — the minimal multixact ID at the start of the backup.
- `tablespace_list` — a list of tablespaces included in the backup.
- `database_list` — a list of databases included in the backup.

`LABEL label`

The name of the backup.

`INCR_MODE incr_mode`

The type of incremental backup. Possible values: PTRACK, DELTA.

`START_LSN start_lsn`

An `XLogRecPtr` value representing LSN at the start of the backup.

`TRANSFER_MODE transfer_mode`

The method to be used for sending data from a server to an application. Possible values:

- `raw` — unpacked data is sent in random blocks of arbitrary size.
- `packed` — packed data is sent in blocks of 128 KB with a common header.

`packed` is the default value.

`TRANSFER_BUFFER_SIZE buffer_size`

A numeric value representing the buffer size. The preset (unchanged) value is 131072 (128 KB).

#### F.44.4.2. `copy_files`

`copy_files VERIFY_CHECKSUMS [TRUE | FALSE], COMPRESS_ALG compress_alg,  
COMPRESS_LVL compress_lvl, TRANSFER_MODE transfer_mode,  
[INCR_MODE incr_mode], [START_LSN start_lsn], [TRANSFER_BUFFER_SIZE buffer_size],  
[WORKER_INFO number_of_workers:worker_id]`

Forwards blocks of data files and WAL files packaged in the CBOR format.

`VERIFY_CHECKSUMS`

A boolean value (`true` or `false`) indicating whether to verify checksums.

`COMPRESS_ALG compress_alg`

The compression algorithm to be used. Possible values: `zlib`, `zstd`, `lz4`, `none`.

`COMPRESS_LVL compress_lvl`

The compression level. Possible values: 1, 2, 3, 4, 5.

`TRANSFER_MODE transfer_mode`

The method to be used for sending data from a server to an application. Possible values:

- `raw` — unpacked data is sent in random blocks of arbitrary size.

- `packed` — packed data is sent in blocks of 128 KB with a common header.

`packed` is the default value.

`INCR_MODE incr_mode`

The type of incremental backup. Possible values: `PTRACK`, `DELTA`.

`START_LSN start_lsn`

An `XLogRecPtr` value representing LSN at the start of the backup.

`TRANSFER_BUFFER_SIZE buffer_size`

A numeric value representing the buffer size. The preset (unchanged) value is 131072 (128 KB).

`WORKER_INFO number_of_workers:worker_id`

The number of workers and the worker ID.

### F.44.4.3. `stop_backup`

```
stop_backup STREAM [TRUE | FALSE], COMPRESS_ALG compress_alg,  
  COMPRESS_LVL compress_lvl,  
  [EXTERNALS externals] [TRANSFER_BUFFER_SIZE buffer_size], [TRANSFER_MODE transfer_mode]
```

Completes the copy process and closes the existing connection. Sends the following data to the application:

- `stop_lsn` — LSN at the end of the backup.
- `stop_tli` — the timeline ID at the end of the backup.
- The `backup.control` file.
- A set of WAL files (only if WAL streaming is enabled).

`STREAM`

A boolean value (`true` or `false`) indicating whether WAL streaming is enabled.

`COMPRESS_ALG compress_alg`

The compression algorithm to be used. Possible values: `zlib`, `zstd`, `lz4`, `none`.

`COMPRESS_LVL compress_lvl`

The compression level. Possible values: 1, 2, 3, 4, 5.

`EXTERNALS externals`

A list of external directories.

`TRANSFER_BUFFER_SIZE buffer_size`

A numeric value representing the buffer size. The preset (unchanged) value is 131072 (128 KB).

`TRANSFER_MODE transfer_mode`

The method to be used for sending data from a server to an application. Possible values:

- `raw` — unpacked data is sent in random blocks of arbitrary size.
- `packed` — packed data is sent in blocks of 128 KB with a common header.

`packed` is the default value.

## F.44.5. Authors

Postgres Professional, Moscow, Russia.

## F.45. pgpro\_cpumeter

`pgpro_cpumeter` is an extension providing access to a new CPU usage monitoring system function. This `pgpro_cpumeter` function continuously collects and records information about CPU cores used by Postgres Pro server processes.

### F.45.1. Installation

The `pgpro_cpumeter` extension is a built-in extension included into Postgres Pro Enterprise. To enable `pgpro_cpumeter`, use the following query:

```
CREATE EXTENSION pgpro_cpumeter;
```

### F.45.2. pgpro\_cpumeter function

The `pgpro_cpumeter` provides the following system function:

`pgpro_cpumeter(OUT start_time timestamptz, OUT end_time timestamptz, OUT user_time int, OUT system_time int, OUT cpus_allowed int, OUT cpus_online int, OUT arch text, OUT machine_id text, OUT system_identifier bigint)` returns setof record

Returns the collected statistics on CPU usage in the following output columns:

`start_time`

The start time of the measurement period. This value is inclusive (`[start_time, end_time)`). It matches the `end_time` of the previous measurement record.

`end_time`

The end time of the measurement period, indicating when the collected information is recorded to the disk. This value is exclusive (`[start_time, end_time)`). It becomes the `start_time` of the subsequent measurement period.

`user_time`

The user CPU time, which is the total CPU time in seconds spent by all Postgres Pro processes in user mode.

`system_time`

The system CPU time, which is the total CPU time in seconds spent by all Postgres Pro processes in system (kernel) mode.

`cpus_allowed`

The number of logical CPU cores available to Postgres Pro processes. This value may be limited, for example, by the `taskset` tool and is typically less than or equal to `cpus_online`.

`cpus_online`

The number of logical CPU cores currently active and available to the operating system. This value may be less than the total number of physical cores in the system, for example, if some cores are disabled.

`arch`

The processor architecture. This value remains constant for the entire database cluster.

machine\_id

The unique identifier of the host stored in the `/etc/machine-id` file. This value may change if the PGDATA directory is moved to a different server.

system\_identifier

The system identifier of the database cluster. This value remains constant for the cluster lifetime, changing only in very limited and exceptional circumstances.

### F.45.3. Limitations and Considerations

When using `pgpro_cpumeter`, consider the following issues:

- The collected statistics are recorded every 10 minutes. This interval cannot be changed.

However, statistics are also recorded at the server shutdown. In this case, the last measurement period may be less than 10 minutes.

At the next server start, `start_time` will not match `end_time` of the previous period. The `start_time` value for the first record will be equal to the server start time.

- If the server crashes, the collected statistics for the most recent measurement period (up to 10 minutes) are lost.

### F.45.4. Example

The example below illustrates how to use `pgpro_cpumeter` and its expected output.

```
postgres=# CREATE EXTENSION pgpro_cpumeter;
CREATE EXTENSION
```

```
postgres=# SELECT * FROM pgpro_cpumeter() ORDER BY start_time ASC LIMIT 5;
      start_time      |      end_time      | user_time |
system_time | cpus_allowed | cpus_online | arch |      machine_id      |
system_identifier

## F.46. pg\_prewarm

The `pg_prewarm` module provides a convenient way to load relation data into either the operating system buffer cache or the Postgres Pro buffer cache. Prewarming can be performed manually using the `pg_prewarm` function, or can be performed automatically by including `pg_prewarm` in [shared\\_preload\\_libraries](#). In the latter case, the system will run a background worker which periodically records the contents of shared buffers in a file called `autoprewarm.blocks` and will, using 2 background workers, reload those same blocks after a restart.

### F.46.1. Functions

```

pg_prewarm(regclass, mode text default 'buffer', fork text default 'main',
    first_block int8 default null,
    last_block int8 default null) RETURNS int8

```

The first argument is the relation to be prewarmed. The second argument is the prewarming method to be used, as further discussed below; the third is the relation fork to be prewarmed, usually `main`. The

fourth argument is the first block number to prewarm (`NULL` is accepted as a synonym for zero). The fifth argument is the last block number to prewarm (`NULL` means prewarm through the last block in the relation). The return value is the number of blocks prewarmed.

There are three available prewarming methods. `prefetch` issues asynchronous prefetch requests to the operating system, if this is supported, or throws an error otherwise. `read` reads the requested range of blocks; unlike `prefetch`, this is synchronous and supported on all platforms and builds, but may be slower. `buffer` reads the requested range of blocks into the database buffer cache.

Note that with any of these methods, attempting to prewarm more blocks than can be cached — by the OS when using `prefetch` or `read`, or by Postgres Pro when using `buffer` — will likely result in lower-numbered blocks being evicted as higher numbered blocks are read in. Prewarmed data also enjoys no special protection from cache evictions, so it is possible that other system activity may evict the newly prewarmed blocks shortly after they are read; conversely, prewarming may also evict other data from cache. For these reasons, prewarming is typically most useful at startup, when caches are largely empty.

`autoprewarm_start_worker()` RETURNS void

Launch the main autoprewarm worker. This will normally happen automatically, but is useful if automatic prewarm was not configured at server startup time and you wish to start up the worker at a later time.

`autoprewarm_dump_now()` RETURNS int8

Update `autoprewarm.blocks` immediately. This may be useful if the autoprewarm worker is not running but you anticipate running it after the next restart. The return value is the number of records written to `autoprewarm.blocks`.

## F.46.2. Configuration Parameters

`pg_prewarm.autoprewarm` (boolean)

Controls whether the server should run the autoprewarm worker. This is on by default. This parameter can only be set at server start.

`pg_prewarm.autoprewarm_interval` (int)

This is the interval between updates to `autoprewarm.blocks`. The default is 300 seconds. If set to 0, the file will not be dumped at regular intervals, but only when the server is shut down.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'pg_prewarm'

pg_prewarm.autoprewarm = true
pg_prewarm.autoprewarm_interval = 300s
```

## F.46.3. Author

Robert Haas <rhaas@postgresql.org>

## F.47. pgpro\_scheduler

`pgpro_scheduler` is a built-in Postgres Pro Enterprise extension for scheduling, monitoring, and managing job execution within the Postgres Pro Enterprise database. With `pgpro_scheduler`, you can:

- Set advanced schedules using `jsonb` objects or `crontab` strings.
- Dynamically calculate the next execution time for repeated jobs.

- Execute SQL commands of the job in a single transaction or in sequential transactions, if required.
- Submit jobs for immediate or delayed one-time execution in parallel with the scheduled jobs.

Unlike external scheduling daemons, `pgpro_scheduler` offers the following benefits:

- Any user can schedule jobs independently.
- Job scheduling can be managed on the fly without restarting the database.
- Scheduling is very lightweight since `pgpro_scheduler` uses background workers to schedule, monitor, and manage job execution. At the same time, `pgpro_scheduler` does not require any client connections for scheduling.
- For enhanced stability, each database has its own supervisor scheduler, with each scheduled job executed by a separate background worker.

### Note

`pgpro_scheduler` waits in the suspended state on a standby server to be started when the standby is promoted to a primary server.

### Note

Note that for all the executed jobs, the `pg_stat_activity` view will still show the name of the database superuser, which is used by the background worker.

## F.47.1. Installation and Setup

The `pgpro_scheduler` extension is included into Postgres Pro Enterprise. Once you have Postgres Pro Enterprise installed, complete the following steps to enable `pgpro_scheduler`:

1. Add `pgpro_scheduler` to the `shared_preload_libraries` parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'pgpro_scheduler'
```

2. Create the `pgpro_scheduler` extension using the following query:

```
CREATE EXTENSION pgpro_scheduler;
```

Make sure to create the `pgpro_scheduler` extension for each database you are planning to use.

Once you complete the installation and setup, configure `pgpro_scheduler` for your database.

## F.47.2. Configuration

You must have superuser rights to configure `pgpro_scheduler`.

To configure `pgpro_scheduler`, modify the following settings in the `postgresql.conf` file:

1. Specify the names of the databases for which you need to schedule jobs, in the comma-separated format:

```
schedule.database = 'database1,database2'
```

2. To control the workload in your system, set the maximum number of background workers that can run simultaneously on each database:

```
schedule.max_workers = 5
```

3. Optionally, set the number of background workers available for one-time job execution:

```
schedule.max_parallel_workers = 3
```

By default, two background workers for one-time jobs are available. These workers are not included into the `schedule.max_workers` number. Thus, one-time jobs can run in parallel with the scheduled jobs even if all the `schedule.max_workers` workers are busy.

4. Run `pg_reload_conf()` for the changes to take effect:

```
SELECT pg_reload_conf();
```

### Important

When setting the `schedule.max_workers` variable, make sure to leave enough workers for the rest of the system as other subsystems may also use background workers. The `schedule.max_workers` value cannot exceed the total number of workers enabled by the `max_worker_processes` Postgres Pro variable.

The `pgpro_scheduler` extension starts a separate background worker for the system, each database, and each executed job. For example, if you work with two databases and set the maximum number of workers and parallel workers to 5 and 3, respectively, `pgpro_scheduler` can use up to 19 workers at peak times: one worker is supervising the system, two workers are monitoring the two databases, and each database uses five workers for job scheduling and three workers for running one-time jobs. If all background workers are busy, the jobs will wait for the next available worker. Scheduled and one-time jobs have separate job queues.

If required, you can later change the number of workers. The running jobs will not be affected.

You can also dynamically configure `pgpro_scheduler` from the command line. In this case, you can set different number of workers for different databases:

```
ALTER SYSTEM SET schedule.database = 'database1,database2';
ALTER DATABASE database1 SET schedule.max_workers = 5;
ALTER DATABASE database2 SET schedule.max_workers = 3;
ALTER SYSTEM SET schedule.max_parallel_workers = 3;
SELECT pg_reload_conf();
```

Once `pgpro_scheduler` is configured, enable it on your system, as follows:

```
SELECT schedule.enable();
```

If this function returns `true`, `pgpro_scheduler` is ready to use, and you can start scheduling jobs as explained in [Section F.47.3.1](#) and [Section F.47.3.2](#).

### Note

If you restart the server, `pgpro_scheduler` is not automatically restarted by default. To change this behavior, you can set the `schedule.auto_enabled` parameter to `on`.

#### See Also

[Section F.47.4.1](#)

## F.47.3. Usage

### F.47.3.1. Creating Scheduled Jobs

To create and schedule a job, run the `create_job()` function that takes scheduling options as a `jsonb` object:

---

```
schedule.create_job(options jsonb)
```

In the `jsonb` object, you must specify one or more SQL commands in the `commands` key, and set the job schedule with at least one of the following keys:

- `dates` — a single date or an array of dates, in the `timestamp with time zone` format
- `cron` — a string, in the `crontab` format. A traditional five-field `crontab` format is used. The first field stands for minute, the second — for hour, the third — for day of the month, the fourth — for month, and the fifth — for day of the week.

```
| minute (0 - 59)
| | hour (0 - 23)
| | | day of the month (1 - 31)
| | | | month (1 - 12)
| | | | | day of the week (0 - 6) (Sunday to Saturday)
| | | | |
* * * * *
```

A six-field `crontab` format can be used alongside the traditional five-field format. In this case the first field stands for second. When you use the six-field format and do not want to specify a second you have to put 0 in the first field.

Alternatively, the following keywords can be used instead of a `crontab` string to specify when the job will be started:

- `@every_second` — each second
- `@hourly` — at the beginning of each hour
- `@daily` — at the beginning of each day
- `@midnight` — at the beginning of each day
- `@weekly` — at the beginning of each week
- `@monthly` — at the beginning of each month
- `@yearly` — at the beginning of each year
- `@annually` — at the beginning of each year
- `rule` — a `jsonb` object that includes one or more of the following keys:
  - `seconds` — seconds; an array of integers in range [0, 59]
  - `minutes` — minutes; an array of integers in range [0, 59]
  - `hours` — hours; an array of integers in range [0, 23]
  - `days` — days of the month; an array of integers in range [1, 31]
  - `months` — months; an array of integers in range [1, 12]
  - `wdays` — days of the week; an array of integers in range [0, 6], where 0 is Sunday.
  - `onstart` — integer value 0 or 1. If `onstart` is set to 1, the job is executed only once when `pg-pro-scheduler` is started.

You can combine `dates`, `cron`, and `rule` scheduling keys for advanced use cases.

As a result, `pgpro_scheduler` creates an active job with the specified schedule and returns the job ID.

### Tip

For simple job schedules, you can use the following shortcut syntax:

Additional Supplied Modules  
and Extensions Shipped in  
postgrespro-ent-14-contrib

```
schedule.create_job(cron, commands)
schedule.create_job(dates, commands)
```

For details, see [schedule.create\\_job\(\)](#) function description.

If required, you can later modify one or more scheduling options with the `set_job_attribute()` or `set_job_attributes()` functions, respectively.

If all background workers are busy at the specified time, the job waits for the next available worker. By default, the job can wait forever. You can limit the maximum wait time by setting the `last_start_available` key, in the [time interval](#) format. If the timeout is reached, `pgpro_scheduler` cancels the job execution.

### Examples:

To run the job every day at 3pm, and, additionally, on December 31, 2017 at 7pm , and on April 4, 2020 at 1pm:

```
SELECT schedule.create_job('{ "commands": "SELECT 15", "cron": "0 15 * * *", "dates":
[ "2017-12-31 19:00", "2020-04-04 13:00" ]}');
```

To limit the wait time for job execution to 30 seconds after the scheduled time:

```
SELECT schedule.create_job('{ "commands": "SELECT pg_sleep(100)", "cron": "15 */2 * *
*", "last_start_available": "30 seconds" }');
```

### Note

Both for scheduled and one-time jobs, you cannot manage their main transactions, namely using `COMMIT` and `ROLLBACK`. However, you can create and manage autonomous transactions.

#### F.47.3.1.1. Specifying the Time Window for Job Execution

In addition to the general schedule, you can specify the timeframe during which the scheduled job can be executed. To ensure that `pgpro_scheduler` only executes the job within the specified time window, define the `start_date` and `end_date` keys, in the timestamp with time zone format. You can set one of these keys only to limit the start or the end time, respectively. If you define a time window for the job, `pgpro_scheduler` will only schedule this job within this time window. If the started job is incomplete when the specified time window ends, `pgpro_scheduler` completes the job and then excludes the job from further scheduling.

### Examples:

To start scheduling the job only after 11am on May 1, 2017:

```
SELECT schedule.create_job('{ "commands": "SELECT now()", "cron": "2 17 * * *",
"start_date": "2017-05-01 11:00" }');
```

To schedule the job in the timeframe from 11am on May 1 to 3pm on June 4, 2017:

```
SELECT schedule.create_job('{ "commands": "SELECT now()", "cron": "2 17 * * *",
"start_date": "2017-05-01 11:00", "end_date": "2017-06-04 15:00" }');
```

#### F.47.3.1.2. Running SQL Commands in Separate Transactions

The `commands` key can have values of text and array types. If you specify several SQL commands as text separated by semicolons, the whole job is executed in a single transaction. If it is critical to perform each SQL command in a separate transaction, pass the SQL commands as an array. You can modify this

behavior by setting the `use_same_transaction` key to `true`. In this case, SQL commands in the array are executed in a single transaction.

### Examples:

To run the whole job in a single transaction:

```
SELECT schedule.create_job('{ "commands": "SELECT 1; SELECT 2; SELECT 3;", "cron": "23
23 */2 * *" }');
```

To run commands in separate transactions:

```
SELECT schedule.create_job('{ "commands": [ "SELECT 1", "SELECT 2", "SELECT 3" ],
"cron": "23 23 */2 * *" }');
```

To run the whole job in a single transaction when passing the commands as an array:

```
SELECT schedule.create_job('{ "commands": [ "SELECT 1", "SELECT 2", "SELECT 3" ],
"cron": "23 23 */2 * *", "use_same_transaction": true }');
```

#### F.47.3.1.3. Calculating the Next Start Time of the Scheduled Job

For repeated jobs, the next start time can be computed by an SQL statement specified in the `next_time_statement` key. In this case, the first job starts on schedule, while all the successive job runs occur at the computed times.

After the job run completes, `pgpro_scheduler` executes the SQL statement in the `next_time_statement` key to calculate the next start time and returns the result, in the `timestamp with time zone` type. If the return value is of a different type or an error occurs, `pgpro_scheduler` marks the job as broken and cancels any further execution. This process is repeated for each successive job run.

### Tip

When the job run completes, `pgpro_scheduler` sets the transaction state in the `schedule.transaction_state` variable, in the text format. You can use this variable in your `next_time_statement` to dynamically calculate the next start time depending on the transaction state. At the time of the `next_time_statement` execution, the `schedule.transaction_state` variable must contain either success or failure state values for the main transaction. Other values may indicate an internal `pgpro_scheduler` error.

### Examples:

To run the job first at 10:45, and then in a day after the job completes:

```
SELECT schedule.create_job('{ "commands": "SELECT random()", "cron": "45 10 * * *",
"next_time_statement": "SELECT now() + '1 day'::interval" }');
```

#### F.47.3.1.4. Setting Additional Conditions for Job Execution

The `pgpro_scheduler` extension enables you to define additional conditions for task execution:

- Set time limits for job execution with the `max_run_time` key. If the execution time is exceeded, `pgpro_scheduler` cancels the job.
- Define the maximum time a scheduled job can wait for execution using the `last_start_available` key. If the timeout is reached, `pgpro_scheduler` cancels the job.
- Schedule a job to be executed with the rights of another user by specifying the `run_as` key. You must have superuser rights to use this key.
- Define an SQL command to execute if the main command fails using the `onrollback` key.

### Examples:

To limit job execution to 5 seconds:

```
SELECT schedule.create_job('{ "commands": "SELECT pg_sleep(10)", "cron": "15 */10 * * *", "max_run_time": "5 seconds" }');
```

To limit the wait time for job execution to 30 seconds after the scheduled time:

```
SELECT schedule.create_job('{ "commands": "SELECT pg_sleep(100)", "cron": "15 */2 * * *", "last_start_available": "30 seconds" }');
```

To start the job with the rights of the `robot` user:

```
SELECT schedule.create_job('{ "commands": "SELECT session_user", "cron": "5 */5 * * *", "run_as": "robot" }');
```

To define a fallback SQL command in case the main command fails:

```
SELECT schedule.create_job('{ "commands": "SELECT ''zzz''", "cron": "55 */12 * * *", "onrollback": "SELECT ''Cannot select zzz''" }');
```

### F.47.3.2. Submitting One-Time Jobs

You can submit jobs for one-time execution using the `schedule.submit_job()` function. Such jobs use a separate pool of background workers defined by the `schedule.max_parallel_workers` variable, and can run in parallel with the scheduled jobs. By default, two one-time jobs can run concurrently. If you submit more jobs, they will wait in the queue for the next available background worker.

To execute a one-time job immediately, pass SQL commands in the `query` argument. For example:

```
schedule.submit_job(query := 'select 1');
```

Instead of passing SQL query parameters directly, you can define numbered placeholders in the `query` argument, such as `$1` and `$2`, and pass an array of parameters in the `params` argument, with each array element corresponding to a placeholder. For brevity, you can omit the `query` and `params` names:

```
schedule.submit_job(query := 'select $1, $2', params := '{"text 1", "text 2"}')
```

To start a one-time job at the specified time, use the `run_after` argument:

```
schedule.submit_job('select ''flowers''', run_after := '2017-03-08 08:00:01');
```

Alternatively, you can delay the job start until the specified jobs are complete using the `depends_on` argument. For example, to run a job after completing the jobs with 23, 15, and 334 IDs, run:

```
schedule.submit_job('select ''well done''', depends_on := '{23, 15, 334}')
```

If required, you can repeat the job execution by passing the `schedule.resubmit()` function as part of the `query` argument. For example:

```
schedule.submit_job('select 1, schedule.resubmit(run_after := ''5'')');
```

The `run_after` argument specifies the time interval before the job is restarted, in seconds. By default, the interval is 1 second.

The resubmitted job cannot be executed more than the number of times set in the `resubmit_limit` argument. If this limit is reached, the job receives the `done` status, with the corresponding error message.

If you want to cancel a resubmitted job, run:

```
schedule.cancel_job(job_id bigint);
```

To monitor one-time jobs, use the [job\\_status](#) and [all\\_job\\_status](#) `pgpro_scheduler` views.

For details on all the functions available for managing one-time jobs, see [Section F.47.4.6.3](#).

### F.47.3.3. Changing and Removing Scheduled Jobs

When you create a new job with the `create_job()` function, the job becomes active and waits for execution based on the specified schedule. Using the job ID returned by the `create_job()` function, you can change the scheduling settings or remove the job from the schedule. To change the specified schedule for the jobs, use `set_job_attribute()` or `set_job_attributes()` functions:

- To modify a single property of the job, run the `set_job_attribute()` function with the job ID, the property name to change, and the new value for this property.
- To modify more than one property of the job, run the `set_job_attributes()` function instead. In this case, you can specify all the job properties at once in a `jsonb` object. For details on all the keys available for job scheduling, see the `create_job()` function description.

To temporarily exclude the job from scheduling, run the `deactivate_job()` function:

```
schedule.deactivate_job(job_id integer)
```

You can re-activate the job later by running the `activate_job()` function:

```
schedule.activate_job(job_id integer)
```

To permanently remove the job from the schedule, run the `drop_job()` function:

```
schedule.drop_job(job_id integer)
```

### F.47.3.4. Monitoring Scheduled Jobs

You must have superuser rights to monitor job execution for the whole system. Otherwise, you can only monitor the jobs that you own. To monitor scheduled jobs, `pgpro_scheduler` provides multiple functions that return `cron_rec` or `cron_job` records:

- `get_job()` — retrieves information about the job.
- `get_owned_cron()` — retrieves the list of jobs owned by user.
- `get_cron()` — retrieves the list of jobs executed by user.
- `get_active_jobs()` — returns the list of jobs executed at the moment of the function call.
- `get_log()` — returns the list of all completed jobs.
- `get_user_log()` — returns list of the completed jobs executed by the specified user.
- `clean_log()` — deletes all records with information about completed jobs.

To learn more about each function, see [Section F.47.4.6](#).

### F.47.3.5. Auditing Job Scheduling

`pgpro_scheduler` enables you to audit job scheduling to rule out human error if you observe unexpected changes in scheduled job execution.

By default, `pgpro_scheduler` does not store information on schedule changes. To enable this feature, set the `schedule.enable_history` parameter to `true`. Once this parameter is enabled, `pgpro_scheduler` stores schedule modifications in the `schedule.cron__history` table, and logs all deleted jobs in the `schedule.cron__deleted` table. Logged history is never deleted from these tables, so a superuser can review schedule changes introduced by all users at any time.

For details on logged information, see [Section F.47.4.5](#).

### F.47.3.6. Scheduling Jobs on a Multi-Master Cluster

Using `pgpro_scheduler`, you can manage scheduled and one-time jobs on a cluster configured with `multimaster`. `pgpro_scheduler` can only manage jobs on the node on which it is installed. Thus, you

must install and enable `pgpro_scheduler` on all nodes on which you would like to schedule jobs. `pgpro_scheduler` instances will manage jobs on different nodes independently, but the executed jobs will be replicated to other nodes.

Even if you are planning to schedule jobs on a single node only, it is recommended to enable `pgpro_scheduler` on several nodes. In this case, if a node with scheduled jobs fails, another `pgpro_scheduler` instance picks up these jobs. If `pgpro_scheduler` is running on more than one node, the node with the smallest node ID is selected. The naming pattern of node IDs is defined by the [schedule.nodename](#) GUC variable.

## F.47.4. Reference

### F.47.4.1. GUC Variables

`schedule.enabled` (boolean)

Deprecated. Specifies whether `pgpro_scheduler` is enabled on your system.

Default: `false`.

For `pgpro_scheduler` 2.5 or higher, you can set the [schedule.auto\\_enabled](#) parameter to control whether `pgpro_scheduler` is enabled at the server start, or use `schedule.enable()/schedule.disable()` functions to enable/disable `pgpro_scheduler` on demand. To check if `pgpro_scheduler` is currently running, use the `schedule.is_enabled()` function.

`schedule.auto_enabled` (boolean)

Specifies whether to enable `pgpro_scheduler` at the server start.

Default: `false`.

`schedule.database` (text)

Specifies the databases for which `pgpro_scheduler` is enabled. Database names must be separated by commas.

Default: empty string.

`schedule.database_to_connect` (text)

The database to which `pgpro_scheduler` gets connected to receive Postgres Pro Enterprise cluster metadata. The specified database cannot be dropped while `pgpro_scheduler` is running. You can change this parameter only when restarting the server.

Default: `postgres`.

`schedule.schema` (text)

Deprecated. Specifies the name of a schema where the scheduler stores its tables and functions. If you need to change the default schema, use [ALTER EXTENSION](#).

Default: `schedule`.

`schedule.nodename` (text)

Specifies the name of the cluster node on which `pgpro_scheduler` is running. Do not change or use this variable if you run a single-server cluster configuration.

On a cluster configured with `multimaster`, the node name is derived from the node ID provided by `multimaster`. For example, if the node ID is 3, the `schedule.nodename` variable is set to `mtm-node-3`. However, if you explicitly set the `schedule.nodename` variable by editing the `postgresql.conf` file

or running the `ALTER` command, `pgpro_scheduler` will ignore the node ID and use the provided value instead.

Default: `primary`.

`schedule.max_workers` (integer)

Specifies the maximum number of simultaneously running scheduled jobs in one database.

Default: 2.

`schedule.max_parallel_workers` (integer)

Specifies the maximum number of parallel threads that can be used for executing one-time jobs.

Default: 2.

`schedule.transaction_state` (text)

An internal variable containing the state of the executed job. `pgpro_scheduler` uses this variable when calculating the next job start time. Possible values are:

- `success` — transaction has finished successfully.
- `failure` — transaction has failed to finish.
- `running` — transaction is in progress.
- `undefined` — transaction has not started yet.

At the time of the `next_time_statement` execution, the `schedule.transaction_state` variable must contain either `success` or `failure` state values. Other values may indicate an internal `pgpro_scheduler` error.

`schedule.enable_history` (boolean)

Log all schedule changes, including the name of the user who initiated the change and the time when this change occurred. If a new job is added, or the schedule of an existing job is modified, this information is stored in the `schedule.cron__history` table. If a job is deleted, this information is stored in the `schedule.cron__deleted` table. If you later disable the `schedule.enable_history` parameter, the history of the already recorded changes is preserved.

Default: `false`

## F.47.4.2. SQL Schema

To store its internal tables and functions, `pgpro_scheduler` uses the `schedule` SQL schema. Direct access to tables is not recommended and should not be attempted. To manage job scheduling, use the functions defined by the `pgpro_scheduler` extension.

## F.47.4.3. SQL Types

`pgpro_scheduler` defines the following types that are used by some of the `pgpro_scheduler` functions.

### F.47.4.3.1. `cron_rec`

This type contains information about the scheduled job.

```
CREATE TYPE schedule.cron_rec AS (  
    id integer,           -- job ID  
    node text,            -- name of the node  
                        -- on which to execute the job  
    name text,            -- job name  
    comments text,        -- comments about the job
```

## Additional Supplied Modules and Extensions Shipped in

postgrespro-ent-14-contrib

---

```

rule jsonb,                -- scheduling rules
commands text[],          -- SQL commands to be executed
run_as text,              -- username of the job executor
owner text,               -- username of the job owner
start_date timestamptz,   -- lower bound of the execution window;
                        -- NULL if unbound
end_date timestamptz,     -- upper bound of the execution window;
                        -- NULL if unbound
use_same_transaction boolean, -- true if an array of SQL
                        -- commands will be executed
                        -- in a single transaction
last_start_available interval, -- maximum wait time for
                        -- the scheduled job if all
                        -- allowed workers are busy
max_run_time interval,    -- maximum execution time
onrollback text,          -- SQL statement to execute
                        -- if the main transaction fails
max_instances int,        -- maximum number of simultaneously
                        -- running job instances
next_time_statement text, -- SQL statement to calculate
                        -- the next start time
active boolean,           -- true if job is scheduled
                        -- successfully
broken boolean            -- true if job has errors in
                        -- configuration that prevented
                        -- its further execution
);

```

### F.47.4.3.2. cron\_job

This type contains information about a particular job execution.

```

CREATE TYPE schedule.cron_job AS(
    cron integer,          -- job id
    node text,             -- name of the node
                        -- on which to execute the job
    scheduled_at timestamptz, -- scheduled execution time
    name text,             -- job name
    comments text,         -- comments about the job
    commands text[],       -- SQL statement to be executed
    run_as text,           -- username of the job executor
    owner text,            -- username of the job owner
    use_same_transaction boolean, -- true if an array of SQL
                        -- commands will be executed
                        -- in a single transaction
    started timestamptz,    -- timestamp of the job execution start
    last_start_available timestamp, -- maximum wait time for
                        -- the scheduled job if all
                        -- allowed workers are busy
    finished timestamptz,   -- timestamp of the job
                        -- execution finish
    max_run_time interval,  -- maximum execution time
    onrollback text,        -- SQL statement to execute if the main
                        -- transaction fails
    next_time_statement text, -- SQL statement to calculate
                        -- the next start time
    max_instances int,      -- the number of simultaneously
                        -- running job instances
    status job_status_t,    -- status of the task:
);

```

```
message text
);
```

#### F.47.4.3.3. `job_status_t`

Enumerated type. Can take the following values:

- `working` — the job is being executed.
- `done` — job execution is complete.
- `error` — job execution has failed.

#### F.47.4.3.4. `job_at_status_t`

Enumerated type. Can take the following values:

- `submitted` — the job is submitted into the queue, but the execution has not started yet.
- `processing` — the job is being executed.
- `done` — job execution is complete.

#### F.47.4.3.5. `timetable_job_type_t`

Enumerated type. Can take the following values:

- `periodical` — a scheduled job.
- `onetime` — a one-time job.

#### F.47.4.3.6. `timetable_job_status_t`

Enumerated type. Can take the following values:

- `inprogress` — the job is being executed.
- `done` — job execution is complete.
- `error` — job execution has failed.
- `submitted` — the job is submitted into the queue, but the execution has not started yet.

### F.47.4.4. Views

`pgpro_scheduler` provides several views for monitoring execution status of one-time jobs.

#### F.47.4.4.1. `job_status` View

Shows the status of one-time jobs belonging to the current user.

**Table F.33. `job_status` View**

| Column Name            | Column Type                           | Description                                          |
|------------------------|---------------------------------------|------------------------------------------------------|
| <code>id</code>        | <code>bigint</code>                   | Job ID.                                              |
| <code>node</code>      | <code>text</code>                     | Name of the node on which the job is being executed. |
| <code>name</code>      | <code>text</code>                     | Name of the job.                                     |
| <code>comments</code>  | <code>text</code>                     | Comments about the job.                              |
| <code>run_after</code> | <code>timestamp with time zone</code> | Timestamp after which the job execution must start.  |
| <code>query</code>     | <code>text</code>                     | SQL commands executed by the job.                    |

Additional Supplied Modules  
and Extensions Shipped in  
postgrespro-ent-14-contrib

| Column Name       | Column Type              | Description                                                                                                                                          |
|-------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| params            | text[]                   | An array of parameters for the SQL query.                                                                                                            |
| depends_on        | bigint[]                 | An array of job IDs on which the job execution depends.                                                                                              |
| run_as            | text                     | User or role whose rights are used to execute the job.                                                                                               |
| attempt           | bigint                   | The number of execution attempts.                                                                                                                    |
| resubmit_limit    | bigint                   | The maximum number of allowed job resubmissions.                                                                                                     |
| max_wait_interval | interval                 | The maximum time interval to postpone the job execution if all background workers are busy at the scheduled moment.                                  |
| max_duration      | interval                 | Time interval during which the job can be executed.                                                                                                  |
| submit_time       | timestamp with time zone | Time when the job was submitted to the execution queue.                                                                                              |
| canceled          | boolean                  | Specifies whether the job was canceled by user.                                                                                                      |
| start_time        | timestamp with time zone | Job execution start time.                                                                                                                            |
| is_success        | boolean                  | <ul style="list-style-type: none"> <li>true — job execution completed successfully.</li> <li>false — job execution completed with errors.</li> </ul> |
| error             | text                     | Error message.                                                                                                                                       |
| done_time         | timestamp with time zone | Time when the job execution completed.                                                                                                               |
| status            | job_at_status_t          | Job status. See the <a href="#">Section F.47.4.3.4</a> for details.                                                                                  |

#### F.47.4.4.2. all\_job\_status View

Shows the status of all one-time jobs. You must have superuser rights to access this view.

**Table F.34. all\_job\_status View**

| Column Name | Column Type              | Description                                          |
|-------------|--------------------------|------------------------------------------------------|
| id          | bigint                   | Job ID.                                              |
| node        | text                     | Name of the node on which the job is being executed. |
| name        | text                     | Name of the job.                                     |
| comments    | text                     | Comments about the job.                              |
| run_after   | timestamp with time zone | Timestamp after which the job execution must start.  |
| query       | text                     | SQL commands executed by the job.                    |
| params      | text[]                   | An array of parameters for the SQL query.            |

| run_as            | text                     | User or role whose rights are used to execute the job.                                                                                                                             |
| owner             | text                     | The user who created the job.                                                                                                                                                      |
| attempt           | bigint                   | The number of execution attempts.                                                                                                                                                  |
| resubmit_limit    | bigint                   | The maximum number of allowed job resubmissions.                                                                                                                                   |
| max_wait_interval | interval                 | The maximum time interval to postpone the job execution for if all background workers are busy at the scheduled moment.                                                            |
| max_duration      | interval                 | Time interval during which the job can be executed.                                                                                                                                |
| submit_time       | timestamp with time zone | Time when the job was submitted to the execution queue.                                                                                                                            |
| canceled          | boolean                  | Specifies whether the job was canceled by user.                                                                                                                                    |
| start_time        | timestamp with time zone | Job execution start time.                                                                                                                                                          |
| is_success        | boolean                  | <ul style="list-style-type: none"> <li>• <code>true</code> — job execution completed successfully.</li> <li>• <code>false</code> — job execution completed with errors.</li> </ul> |
| error             | text                     | Error message.                                                                                                                                                                     |
| done_time         | timestamp with time zone | Time when the job execution completed.                                                                                                                                             |
| status            | job_at_status_t          | Job status. See the <a href="#">Section F.47.4.3.4</a> for details.                                                                                                                |

## F.47.4.5. Audit Tables

The following tables store all schedule changes if the `schedule.enable_history` parameter is set to `true`. If you later disable the `schedule.enable_history` parameter, the history of the already recorded changes is preserved.

### F.47.4.5.1. `schedule.cron_history` Table

Registers job scheduling changes. Whenever a new job is scheduled, or the schedule for an existing job is changed, a new row is inserted into this table to record the following information:

- All details about the scheduled job, as defined by the `cron_rec` data type. For details on the `cron_rec` type, see [Section F.47.4.3](#).
- `submitter` — name of the user who updated the schedule.
- `version_id` — a unique ID for each registered change in the schedule.
- `submit_time` — time when the schedule was updated.

### F.47.4.5.2. `schedule.cron_deleted` Table

Registers all jobs that were removed from the schedule:

- `cron` — ID of the deleted job.

- `submitter` — name of the user who deleted the job.
- `submit_time` — time when the job was deleted.

#### F.47.4.6. Functions

`pgpro_scheduler` provides two separate sets of functions for managing scheduled and one-time jobs, as well as several common functions that can toggle `pgpro_scheduler` on and off for your database and show the current status of the extension:

- [Section F.47.4.6.1](#)
- [Section F.47.4.6.2](#)
- [Section F.47.4.6.3](#)
- [Section F.47.4.6.5](#)

### Important

With each job, you can only use the function specifically tailored for this job type.

##### F.47.4.6.1. Common Functions

These functions facilitate `pgpro_scheduler` management.

`schedule.enable()`

Enables `pgpro_scheduler` for the current Postgres Pro Enterprise instance.

Return values:

- `true` if `pgpro_scheduler` is enabled and ready to use.
- `false` if the command has failed.

`schedule.is_enabled()`

Checks whether `pgpro_scheduler` is enabled.

Return values:

- `true` if `pgpro_scheduler` is enabled and ready to use.
- `false` if `pgpro_scheduler` is not currently running.

`schedule.disable()`

Disables `pgpro_scheduler` for the current Postgres Pro Enterprise instance.

Return values:

- `true` if `pgpro_scheduler` is disabled.
- `false` if the command has failed.

`schedule.start()`

Launches `pgpro_scheduler` for the currently connected database.

Return values:

- `true` — `pgpro_scheduler` started successfully.
- `false` — if the command has failed, or `pgpro_scheduler` is already started.

`schedule.stop()`

Stops `pgpro_scheduler` for the currently connected database.

Return values:

- `true` — `pgpro_scheduler` is stopped.
- `false` — if the command has failed, or `pgpro_scheduler` is not running.

`schedule.status()`

Returns the status of `pgpro_scheduler` background workers:

- `pid` — process ID of the background worker. If the process ID is `NULL`, the background worker is not running.
- `database` — name of the database to which the background worker is connected.
- `type` — type of the background worker:
  - `supervisor` — distributes the scheduled jobs between the databases.
  - `database manager` distributes the scheduled jobs within the database.
  - `cron job executor` executes a scheduled job.
  - `at job executor` executes a one-time job.

`schedule.version()`

Returns `pgpro_scheduler` version.

#### F.47.4.6.2. Functions for Managing Scheduled Jobs

`schedule.create_job(options jsonb)`

Creates an active job and returns the job ID.

##### Alternative Syntax:

```
schedule.create_job(cron text, commands text [, node text])
schedule.create_job(cron text, commands text[] [, node text])
schedule.create_job(dates timestamp with time zone, commands text [, node text])
schedule.create_job(dates timestamp with time zone, commands text[] [, node text])
schedule.create_job(dates timestamp with time zone[], commands text [, node text])
schedule.create_job(dates timestamp with time zone[], commands text[] [, node text])
```

Arguments:

- `options` — a `jsonb` object defining all the job properties. You do not need to define other parameters if the `data` is set. All the available `jsonb` keys are listed in [Table F.35](#).

Type: `jsonb`

- `cron` — a crontab-like string defining the job schedule.

Type: `text`

- `dates` — the exact date or an array of dates for job execution.

Type: `timestamp with time zone, timestamp with time zone[]`

- `commands` — SQL statement to execute. You can pass one or more SQL commands separated by semicolons, or an array of SQL commands. When passed as an array, SQL commands are executed in separate transactions.

Type: `text, text[]`

- `node` — the name of the node on which the scheduled jobs run. Optional. You may need to specify this argument if you are scheduling jobs on a multi-master cluster.

Type: `text`

Return values:

- ID of the created job.

**Table F.35. jsonb Keys for Job Scheduling**

| Key   | Type                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------|---------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cron  | text                                                    | <p>A crontab-like string defining the job schedule. A traditional five-field or nonstandard six-field (seconds in the first field) crontab format may be used. You can combine <code>cron</code> with <code>rule</code> and <code>dates</code> keys, but at least one of them is mandatory. Alternatively, the following keywords can be used instead of a crontab string to specify when the job will be started:</p> <ul style="list-style-type: none"> <li>• <code>@every_second</code> — each second</li> <li>• <code>@hourly</code> — at the beginning of each hour</li> <li>• <code>@daily</code> — at the beginning of each day</li> <li>• <code>@midnight</code> — at the beginning of each day</li> <li>• <code>@weekly</code> — at the beginning of each week</li> <li>• <code>@monthly</code> — at the beginning of each month</li> <li>• <code>@yearly</code> — at the beginning of each year</li> <li>• <code>@annually</code> — at the beginning of each year</li> </ul> |
| dates | timestamp with time zone,<br>timestamp with time zone[] | <p>The exact date or an array of dates when the scheduled job will be executed. You can combine <code>dates</code> with <code>rule</code> and <code>cron</code> keys, but at least one of them is mandatory.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| rule  | jsonb                                                   | <p>A jsonb object defining the job schedule. Mandatory, if both <code>cron</code> and <code>dates</code> keys are undefined. The <code>rule</code> object includes one or more of the following keys:</p> <ul style="list-style-type: none"> <li>• <code>seconds</code> — seconds; an array of integers in range [0, 59]</li> <li>• <code>minutes</code> — minutes; an array of integers in range [0, 59]</li> <li>• <code>hours</code> — hours; an array of integers in range [0, 23]</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Key                               | Type                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   |                                       | <ul style="list-style-type: none"> <li><code>days</code> — days of the month; an array of integers in range [1, 31]</li> <li><code>months</code> — months; an array of integers in range [1, 12]</li> <li><code>wdays</code> — days of the week; an array of integers in range [0, 6], where 0 is Sunday.</li> <li><code>onstart</code> — integer value 0 or 1. If <code>onstart</code> is set to 1, the job is executed only once when <code>pgpro_scheduler</code> is started.</li> </ul> |
| <code>commands</code>             | <code>text, text[]</code>             | SQL statements to execute. You can pass one or more SQL statements separated by semicolons, or an array of SQL statements. When passed as an array, SQL statements are executed in separate transactions by default. You can change this behavior by setting the <code>use_same_transaction</code> key.                                                                                                                                                                                     |
| <code>name</code>                 | <code>text</code>                     | Optional. Job name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>node</code>                 | <code>text</code>                     | Optional. The name of the node on which the scheduled jobs run. You may need to specify this argument if you are scheduling jobs on a multi-master cluster.                                                                                                                                                                                                                                                                                                                                 |
| <code>comments</code>             | <code>text</code>                     | Optional. Comments about the scheduled job.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>run_as</code>               | <code>text</code>                     | Optional. The user whose rights are used to execute the job.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>start_date</code>           | <code>timestamp with time zone</code> | Optional. The start of the time-frame when the scheduled job can be executed. This key can be <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                           |
| <code>end_date</code>             | <code>timestamp with time zone</code> | Optional. The end of the time-frame when the scheduled job can be executed. This key can be <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                             |
| <code>use_same_transaction</code> | <code>boolean</code>                  | Optional. If set to <code>true</code> , forces an array of SQL statements to be executed in a single transaction. Default: <code>false</code>                                                                                                                                                                                                                                                                                                                                               |
| <code>last_start_available</code> | <code>interval</code>                 | Optional. The maximum time interval to postpone the job execution for if all background workers are busy at the scheduled moment. For example, if                                                                                                                                                                                                                                                                                                                                           |

| Key                              | Type                  | Description                                                                                                                                                                             |
|----------------------------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                  |                       | this key is set to '00:02:34', the job will wait for 2 minutes 34 seconds. If this key is <code>NULL</code> or not set, the job can wait forever. Default: <code>NULL</code> .          |
| <code>max_instances</code>       | <code>integer</code>  | Optional. The maximum number of job instances that can be executed simultaneously. Default: 1.                                                                                          |
| <code>max_run_time</code>        | <code>interval</code> | Optional. The maximum time interval during which the scheduled job can be executed. If this key is <code>NULL</code> or not set, there are no time limits. Default: <code>NULL</code> . |
| <code>onrollback</code>          | <code>text</code>     | Optional. SQL statement to be executed if the main transaction fails.                                                                                                                   |
| <code>next_time_statement</code> | <code>text</code>     | Optional. SQL statement to calculate the start time for the next job execution. For details, see <a href="#">Section F.47.3.1.3</a> .                                                   |

```
schedule.set_job_attributes(job_id integer, data jsonb)
```

Updates properties of the existing job.

Arguments:

- `job_id` — identifier of the existing job.
- `data` — a `jsonb` object with properties to be edited. For the list of keys and their structure, see [Table F.35](#).

Return values:

- `true` — job properties were updated successfully.
- `false` — job properties were not updated.

To update the job properties, you must be the owner of the job or have superuser rights.

```
schedule.set_job_attribute(job_id integer, name text, value text || anyarray)
```

Updates a property of the existing job.

Arguments:

- `job_id` — identifier of the existing job.
- `name` — property name.
- `value` — property value.

See [Table F.35](#) for the list of job properties you can update. Some values are of array types. They should be passed as an array. If a value of a wrong type is passed, an exception is raised.

Return values:

- `true` — job property was updated successfully.
- `false` — job property was not updated.

To update the job properties, you must be the owner of the job or have superuser rights.

`schedule.deactivate_job(job_id integer)`

Deactivates the job and suspends its further scheduling and execution.

Arguments:

- `job_id` — identifier of the existing job.

Return values:

- `true` — the job is deactivated successfully.
- `false` — job deactivation failed.

`schedule.activate_job(job_id integer)`

Activates a job and starts its scheduling and execution.

Arguments:

- `job_id` — identifier of the existing job.

Return values:

- `true` — the job was activated successfully.
- `false` — job activation failed.

`schedule.drop_job(job_id integer)`

Deletes a job.

Arguments:

- `job_id` — identifier of the existing job.

Return values:

- `true` — the job was deleted successfully.
- `false` — job was not deleted.

`schedule.get_job(job_id integer)`

Returns information about the specified job.

Arguments:

- `job_id` — identifier of the existing job.

Return values:

- An object of type `cron_rec`.

For details on the `cron_rec` type, see [Section F.47.4.3](#).

`schedule.get_owned_cron(username text)`

Retrieves the list of jobs owned by the specified user.

Arguments:

- `username` — username, optional.

Return values:

- A set of records of type `cron_rec`. These records contain information about all jobs owned by the specified user. If the `username` is omitted, the session username is used. You must have superuser rights to retrieve jobs owned by another user.

For details on the `cron_rec` type, see [Section F.47.4.3](#).

`schedule.get_cron()`

Retrieves the list of jobs executed by the session user.

Return values:

- A set of records of type `cron_rec`. These records contain information about all jobs executed by the session user. You must have superuser rights to retrieve the jobs.

For details on the `cron_rec` type, see [Section F.47.4.3](#).

```
schedule.get_active_jobs(username text)
```

Returns the list of jobs currently being executed by the specified user.

Arguments:

- *username* — username, optional.

If *username* is omitted, the session username is used. You must have superuser rights to retrieve jobs executed by another user.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see [Section F.47.4.3](#).

```
schedule.get_active_jobs()
```

Returns the list of jobs being currently executed. You must have superuser rights to call this function.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see [Section F.47.4.3](#).

```
schedule.get_log()
```

Returns the list of all completed jobs. You must have superuser rights to call this function.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see [Section F.47.4.3](#).

```
schedule.get_user_log(username text)
```

Returns the list of completed jobs executed by the specified user.

Arguments:

- *username* — username, optional.

If *username* is omitted, the session username is used. You must have superuser rights to retrieve the list of jobs executed by another user.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see [Section F.47.4.3](#).

```
schedule.clean_log()
```

Deletes all records with information about the completed jobs. You must have superuser rights to call this function.

Return values:

- The number of records deleted.

```
schedule.nodename()
```

Returns the current node name.

#### F.47.4.6.3. Functions for Managing One-Time Jobs

`schedule.submit_job(query text [options...])`

Submits a job for immediate or delayed one-time execution. By default, the job is scheduled for immediate execution and can run in parallel with other scheduled jobs. To submit a job with a delayed start, you can set the execution start time using the `run_after` argument, or pass an array of job IDs in the `depends_on` argument to schedule job execution right after these jobs are complete.

##### Arguments:

- `query` — SQL commands to execute.

Type: text

- `params` — an array of parameters for the SQL query that can substitute numbered placeholders in the `query` argument, such as \$1, \$2, etc. Default: NULL

Type: text[]

- `run_after` — a timestamp after which the job execution starts. If this argument is set to NULL, the job is scheduled for immediate execution. You can also use the `depends_on` argument to delay the job start. Default: NULL

Type: timestamp with time zone

- `node` — the name of the node on which to execute the job. Default: NULL

Type: text

- `max_duration` — the maximum time interval during which the job can be executed. If this time is exceeded, the job is forced to stop. If this argument is NULL or not set, there are no time limits. Default: NULL

Type: interval

- `max_wait_interval` — the maximum time interval to postpone the job execution for if all background workers are busy at the scheduled moment. For example, if this key is set to '00:02:34', the job will wait for 2 minutes 34 seconds. If this key is NULL or not set, the job can wait forever. Default: NULL

Type: interval

- `run_as` — user or role whose rights are used to execute the job. If `run_as` is set to NULL, the job is executed with the rights of the current user. You must have superuser rights to set this argument. Default: NULL

Type: text

- `depends_on` — an array of job IDs. The created job starts immediately after the specified jobs complete the execution. This argument is an alternative to `run_after`. Default: NULL

Type: bigint[]

- `name` — name of the job. Default: NULL

Type: text

- `comments` — comments about the job.

Type: text

- `resubmit_limit` — maximum number of times the job can be resubmitted for execution. See the `schedule.resubmit()` function for details. Default: 100

Type: bigint

##### Return values:

- ID of the created job.

Type: bigint

`schedule.get_self_id()`

Returns the ID of the job, in the context of which it was called. The returned ID is of the `bigint` type. This function must be called inside the *query* of the `schedule.submit_job()` function. Otherwise, an exception is raised.

Return values:

- Job ID.

`schedule.cancel_job(job_id bigint)`

Cancels all subsequent runs of the specified job. If the job is currently being executed, it will not be interrupted, but cannot be resubmitted. You must have superuser rights or be the owner of the job to call this function.

Arguments:

- *job\_id* — identifier of the job to cancel.

Return values:

- `true` if the operation completed successfully.
- `false` if the operation failed.

`schedule.resubmit(run_after interval default NULL)`

Sets the start time for the next execution of the job, without interrupting the current job run. This function must be called inside the *query* argument of the `schedule.submit_job()` function. Otherwise, an exception is raised. If this function is called several times within a single job execution, only the last function call is taken into account.

Arguments:

- *run\_after* — time interval after which the job will be resubmitted for execution. If the time interval is less than a second but greater than zero, it is rounded to 1 second. Intervals longer than 1 second are rounded to integral values. If 0 is passed, the job is resubmitted immediately after execution. Default: 1 second

Type: interval

Return values:

- The number of seconds after which the job will be resubmitted for execution.

#### F.47.4.6.4. Cleanup Functions

When many one-time jobs are submitted, the `schedule.at_jobs_done` table may grow rapidly. To clean up this table, `pgpro_scheduler` provides the following functions with the same name but different argument types:

`schedule.clean_at_jobs_done(older_than interval, delete_failed_tasks boolean, default NULL)`

`schedule.clean_at_jobs_done(older_than timestamp with time zone, delete_failed_tasks boolean, default NULL)`

Delete all records in `schedule.at_jobs_done` that are older than either a specified timestamp or a specified interval relative to the current time.

Arguments:

- *older\_than* — an interval or a timestamp for cleanup. Records older than this value will be deleted.

Type: interval, timestamp with time zone

- `delete_failed_tasks` — specifies whether to delete failed jobs. Default: `false`.

Type: boolean

Return values:

- The number of deleted records.

These functions can be called manually or scheduled using cron jobs in the `pgpro_scheduler` interface.

#### F.47.4.6.5. Functions for Managing Scheduled and One-Time Jobs

`schedule.timetable(start_time timestamp with time zone, end_time timestamp with time zone)`

Returns a table, which describes all the jobs, both repeated and one-time, that are scheduled to execute within the specified time interval.

**Table F.36. `schedule.timetable` Columns**

| Column Name               | Column Type                           | Description                                                     |
|---------------------------|---------------------------------------|-----------------------------------------------------------------|
| <code>id</code>           | <code>bigint</code>                   | Job ID, which is unique for the jobs of this type.              |
| <code>type</code>         | <code>timetable_job_type_t</code>     | Job type. See <a href="#">Section F.47.4.3.5</a> for details.   |
| <code>node</code>         | <code>text</code>                     | Name of the node on which the job is being executed.            |
| <code>name</code>         | <code>text</code>                     | Name of the job.                                                |
| <code>comments</code>     | <code>text</code>                     | Comments about the job.                                         |
| <code>commands</code>     | <code>text[]</code>                   | An array of SQL commands executed by the job.                   |
| <code>scheduled_at</code> | <code>timestamp with time zone</code> | Scheduled job execution time.                                   |
| <code>start_time</code>   | <code>timestamp with time zone</code> | Job execution start time.                                       |
| <code>done_time</code>    | <code>timestamp with time zone</code> | Time when the job execution completed.                          |
| <code>status</code>       | <code>timetable_job_status_t</code>   | Job status. See <a href="#">Section F.47.4.3.6</a> for details. |
| <code>error</code>        | <code>text</code>                     | Error message.                                                  |

### F.47.5. Authors

Postgres Professional, Moscow, Russia

## F.48. `pg_query_state`

The `pg_query_state` module provides facility to know the current state of query execution on working backend.

### F.48.1. Overview

Each non-utility query statement (SELECT/INSERT/UPDATE/DELETE) after optimization/planning stage is translated into plan tree, which is kind of imperative representation of declarative SQL query. EXPLAIN ANALYZE request allows to demonstrate execution statistics gathered from each node of plan tree (full time of execution, number of rows emitted to upper nodes, etc). But this statistics is collected after execution of query. This module allows to show actual statistics of query running on external backend. At that, format of resulting output is almost identical to ordinal EXPLAIN ANALYZE. Thus users are able

to track of query execution in progress. In fact, this module is able to explore external backend and determine its actual state. Particularly it's helpful when backend executes a heavy query or gets stuck.

## F.48.2. Use cases

Using this module there can help in the following things:

- detect a long query (along with other monitoring tools);
- supervise query execution.

## F.48.3. Installation

To install `pg_query_state`, complete the following steps:

1. Add the library name to the `shared_preload_libraries` parameter in the `postgresql.conf` file as follows:

```
shared_preload_libraries = 'pg_query_state'
```

2. Reload the database server for the changes to take effect.
3. Create the `pg_query_state` extension using the following query:

```
CREATE EXTENSION pg_query_state;
```

4. If you need to upgrade the `pg_query_state` extension, use `ALTER EXTENSION UPDATE`.

## F.48.4. Functions

### F.48.4.1. `pg_query_state`

```
pg_query_state (integer pid,  
                verbose boolean DEFAULT FALSE,  
                costs boolean DEFAULT FALSE,  
                timing boolean DEFAULT FALSE,  
                buffers boolean DEFAULT FALSE,  
                triggers boolean DEFAULT FALSE,  
                format text DEFAULT 'text')  
returns TABLE (pid integer,  
                frame_number integer,  
                query_text text,  
                plan text,  
                leader_pid integer)
```

Extract current query state from backend with specified `pid`. Since parallel query can spawn multiple workers and function call causes nested subqueries so that state of execution may be viewed as stack of running queries, return value of `pg_query_state` has type `TABLE (pid integer, frame_number integer, query_text text, plan text, leader_pid integer)`. It represents tree structure consisting of leader process and its spawned workers identified by `pid`. Each worker refers to leader through `leader_pid` column. For leader process the value of this column is `null`. The state of each process is represented as stack of function calls. Each frame of that stack is specified as correspondence between `frame_number` starting from zero, `query_text` and `plan` with online statistics columns.

Thus, user can see the states of main query and queries generated from function calls for leader process and all workers spawned from it.

In process of execution some nodes of plan tree can take loops of full execution. Therefore statistics for each node consists of two parts: average statistics for previous loops just like in `EXPLAIN ANALYZE` output and statistics for current loop if node have not finished.

Optional arguments:

- `verbose` - use `EXPLAIN VERBOSE` for plan printing;
- `costs` - costs for each node;

- `timing` - print timing data for each node, if collecting of timing statistics is turned off on called side resulting output will contain WARNING message `timing statistics disabled`;
- `buffers` - print buffers usage, if collecting of buffers statistics is turned off on called side resulting output will contain WARNING message `buffers statistics disabled`;
- `triggers` - include triggers statistics in result plan trees;
- `format` - EXPLAIN format to be used for plans printing, possible values: `text`, `xml`, `json`, `yaml`.

If callable backend is not executing any query the function prints INFO message about backend's state taken from `pg_stat_activity` view if it exists there.

Calling role have to be superuser or member of the role whose backend is being called. Otherwise function prints ERROR message `permission denied`.

#### F.48.4.2. `pg_progress_bar`

```
pg_progress_bar (integer pid)
    returns FLOAT
```

Returns the current progress of query execution. This function extracts the state of the current query from the backend process with the specified `pid`. Then, it collects the actual and expected row counts from all plan nodes, and computes the overall progress ratio for the entire execution tree. As a result, the function returns a numeric value from 0 to 1 that means the query execution progress.

This function can be used in the Postgres Pro GUI to display the graphical progress bar indicator.

If there is no information about the current query state or it is impossible to calculate the query execution progress, the corresponding message is displayed.

This function can be called only by members of the role that owns the backend process or superusers.

#### F.48.4.3. `pg_progress_bar_visual`

```
pg_progress_bar_visual (integer pid,
                        integer delay)
    returns VOID
```

Cyclically calculates the current progress of query execution and prints it in the text form. The function extracts the state of the current query from the backend process with the specified `pid` with the interval defined in the `delay` parameter (in seconds).

This function is a cyclic version of the `pg_progress_bar` function but returns `void`. Unlike `pg_progress_bar`, the `pg_progress_bar_visual` function can be used to track the query execution progress without using the GUI.

If there is no information about the current query state or it is impossible to calculate the query execution progress, the corresponding message is displayed.

This function can be called only by members of the role that owns the backend process or superusers.

### F.48.5. Configuration settings

There are several user-accessible GUC variables designed to toggle the whole module and the collecting of specific statistic parameters while query is running:

- `pg_query_state.enable` - disable (or enable) `pg_query_state` completely, default value is `true`
- `pg_query_state.enable_timing` - collect timing data for each node, default value is `false`
- `pg_query_state.enable_buffers` - collect buffers usage, default value is `false`

These parameters are set on called side before running any queries whose states are attempted to extract. WARNING: if `pg_query_state.enable_timing` is turned off the calling side cannot get time statistics, similarly for `pg_query_state.enable_buffers` parameter.

### F.48.6. Usage Examples

Set maximum number of parallel workers on `gather` node equals 2:

Additional Supplied Modules  
and Extensions Shipped in  
postgrespro-ent-14-contrib

---

```
postgres=# set max_parallel_workers_per_gather = 2;
```

Assume one backend with pid = 49265 performs a simple query:

```
postgres=# select pg_backend_pid();
pg_backend_pid
-----
    49265
(1 row)
postgres=# select count(*) from foo join bar on foo.c1=bar.c1;
```

Other backend can extract intermediate state of execution that query:

```
postgres=# \x
postgres=# select * from pg_query_state(49265);
-[ RECORD
  1 ]+-----
pid          | 49265
frame_number | 0
query_text   | select count(*) from foo join bar on foo.c1=bar.c1;
plan         | Finalize Aggregate (Current loop: actual rows=0, loop number=1)
              |
              |      -> Gather (Current loop: actual rows=0, loop number=1)
              |
              |      Workers Planned: 2
              |
              |      Workers Launched: 2
              |
              |      -> Partial Aggregate (Current loop: actual rows=0, loop
number=1)          |
              |      -> Nested Loop (Current loop: actual rows=12, loop
number=1)          |
              |      Join Filter: (foo.c1 = bar.c1)
              |
              |      Rows Removed by Join Filter: 5673232
              |
              |      -> Parallel Seq Scan on foo (Current loop: actual
rows=12, loop number=1)
              |
              |      -> Seq Scan on bar (actual rows=500000 loops=11)
              |      (Current loop: actual rows=173244, loop number=12)
leader_pid   | (null)
-[ RECORD
  2 ]+-----
pid          | 49324
frame_number | 0
query_text   | <parallel query>
plan         | Partial Aggregate (Current loop: actual rows=0, loop number=1)
              |
              |      -> Nested Loop (Current loop: actual rows=10, loop number=1)
              |
              |      Join Filter: (foo.c1 = bar.c1)
              |
              |      Rows Removed by Join Filter: 4896779
              |
              |      -> Parallel Seq Scan on foo (Current loop: actual rows=10, loop
number=1)          |
              |      -> Seq Scan on bar (actual rows=500000 loops=9) (Current loop:
actual rows=396789, loop number=10)
```

Additional Supplied Modules  
and Extensions Shipped in  
postgrespro-ent-14-contrib

```

leader_pid | 49265
-[ RECORD
 3 ]+-----
pid         | 49323
frame_number | 0
query_text  | <parallel query>
plan        | Partial Aggregate (Current loop: actual rows=0, loop number=1)
              +
              | -> Nested Loop (Current loop: actual rows=11, loop number=1)
              +
              |         Join Filter: (foo.c1 = bar.c1)
              +
              |         Rows Removed by Join Filter: 5268783
              +
              |         -> Parallel Seq Scan on foo (Current loop: actual rows=11, loop
number=1)
              +
              |         -> Seq Scan on bar (actual rows=500000 loops=10) (Current loop:
actual rows=268794, loop number=11)
leader_pid  | 49265

```

In example above working backend spawns two parallel workers with pids 49324 and 49323. Their leader\_pid column's values clarify that these workers belong to the main backend. Seq Scan node has statistics on passed loops (average number of rows delivered to Nested Loop and number of passed loops are shown) and statistics on current loop. Other nodes has statistics only for current loop as this loop is first (loop number = 1).

Assume first backend executes some function:

```
postgres=# select n_join_foo_bar();
```

Other backend can get the follow output:

```

postgres=# select * from pg_query_state(49265);
-[ RECORD
 1 ]+-----
pid         | 49265
frame_number | 0
query_text  | select n_join_foo_bar();
plan        | Result (Current loop: actual rows=0, loop number=1)
leader_pid  | (null)
-[ RECORD
 2 ]+-----
pid         | 49265
frame_number | 1
query_text  | SELECT (select count(*) from foo join bar on foo.c1=bar.c1)
plan        | Result (Current loop: actual rows=0, loop number=1)
              +
              |   InitPlan 1 (returns $0)
              +
              |   -> Aggregate (Current loop: actual rows=0, loop number=1)
              +
              |   -> Nested Loop (Current loop: actual rows=51, loop number=1)
              +
              |         Join Filter: (foo.c1 = bar.c1)
              +
              |         Rows Removed by Join Filter: 51636304
              +

```

**Additional Supplied Modules  
and Extensions Shipped in  
postgrespro-ent-14-contrib**

|                                            |  |                                                        |
|--------------------------------------------|--|--------------------------------------------------------|
| number=1)                                  |  | -> Seq Scan on bar (Current loop: actual rows=52, loop |
|                                            |  | +                                                      |
| loop: actual rows=636355, loop number=52)+ |  | -> Materialize (actual rows=1000000 loops=51) (Current |
| rows=1000000, loop number=1)               |  | -> Seq Scan on foo (Current loop: actual               |
| leader_pid                                 |  | (null)                                                 |

First row corresponds to function call, second - to query which is in the body of that function.

We can get result plans in different format (e.g. json):

```
postgres=# select * from pg_query_state(pid := 49265, format := 'json');
-[ RECORD 1 ]+-----+
pid          | 49265
frame_number | 0
query_text   | select * from n_join_foo_bar();
plan         | {
              |   "Plan": {
              |     "Node Type": "Function Scan",
              |     "Parallel Aware": false,
              |     "Function Name": "n_join_foo_bar",
              |     "Alias": "n_join_foo_bar",
              |     "Current loop": {
              |       "Actual Loop Number": 1,
              |       "Actual Rows": 0
              |     }
              |   }
              | }
leader_pid   | (null)
-[ RECORD 2 ]+-----+
pid          | 49265
frame_number | 1
query_text   | SELECT (select count(*) from foo join bar on foo.c1=bar.c1)
plan         | {
              |   "Plan": {
              |     "Node Type": "Result",
              |     "Parallel Aware": false,
              |     "Current loop": {
              |       "Actual Loop Number": 1,
              |       "Actual Rows": 0
              |     },
              |     "Plans": [
              |       {
              |         "Node Type": "Aggregate",

## F.48.7. Progress Bar Usage Examples

The first backend process executes the following sample query:

```
postgres=# insert into table_name select generate_series(1,10000000);
```

Another backend process can get the execution process of the query above as follows:

```
postgres=# SELECT pid FROM pg_stat_activity where query like 'insert%';
 pid
-----
 23877
(1 row)
```

```
postgres=# SELECT pg_progress_bar(23877);
 pg_progress_bar
-----
      0.6087927
(1 row)
```

To display a visual representation of the query execution progress, run the following query:

```
postgres=# SELECT pg_progress_bar_visual(23877, 1);
Progress = 0.043510
Progress = 0.085242
Progress = 0.124921
Progress = 0.168168
Progress = 0.213803
Progress = 0.250362
Progress = 0.292632
Progress = 0.331454
Progress = 0.367509
Progress = 0.407450
Progress = 0.448646
Progress = 0.488171
Progress = 0.530559
Progress = 0.565558
Progress = 0.608039
Progress = 0.645778
Progress = 0.654842
Progress = 0.699006
Progress = 0.735760
Progress = 0.787641
Progress = 0.832160
Progress = 0.871077
Progress = 0.911858
Progress = 0.956362
Progress = 0.995097
Progress = 1.000000
 pg_progress_bar_visual
-----
                        1
(1 row)
```

## F.49. pgrowlocks

The `pgrowlocks` module provides a function to show row locking information for a specified table.

By default use is restricted to superusers, members of the `pg_stat_scan_tables` role, and users with `SELECT` permissions on the table.

### F.49.1. Overview

`pgrowlocks(text)` returns setof record

The parameter is the name of a table. The result is a set of records, with one row for each locked row within the table. The output columns are shown in [Table F.37](#).

**Table F.37. pgrowlocks Output Columns**

| Name       | Type      | Description                                                                                                                                   |
|------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| locked_row | tid       | Tuple ID (TID) of locked row                                                                                                                  |
| locker     | xid       | Transaction ID of locker, or multixact ID if multitransaction                                                                                 |
| multi      | boolean   | True if locker is a multitransaction                                                                                                          |
| xids       | xid[]     | Transaction IDs of lockers (more than one if multitransaction)                                                                                |
| modes      | text[]    | Lock mode of lockers (more than one if multitransaction), an array of Key Share, Share, For No Key Update, No Key Update, For Update, Update. |
| pids       | integer[] | Process IDs of locking backends (more than one if multitransaction)                                                                           |

`pgrowlocks` takes `AccessShareLock` for the target table and reads each row one by one to collect the row locking information. This is not very speedy for a large table. Note that:

1. If an `ACCESS EXCLUSIVE` lock is taken on the table, `pgrowlocks` will be blocked.
2. `pgrowlocks` is not guaranteed to produce a self-consistent snapshot. It is possible that a new row lock is taken, or an old lock is freed, during its execution.

`pgrowlocks` does not show the contents of locked rows. If you want to take a look at the row contents at the same time, you could do something like this:

```
SELECT * FROM accounts AS a, pgrowlocks('accounts') AS p
WHERE p.locked_row = a.ctid;
```

Be aware however that such a query will be very inefficient.

## F.49.2. Sample Output

```
=# SELECT * FROM pgrowlocks('t1');
locked_row | locker | multi | xids | modes | pids
-----+-----+-----+-----+-----+-----
(0,1)      | 609   | f     | {609} | {"For Share"} | {3161}
(0,2)      | 609   | f     | {609} | {"For Share"} | {3161}
(0,3)      | 607   | f     | {607} | {"For Update"} | {3107}
(0,4)      | 607   | f     | {607} | {"For Update"} | {3107}
(4 rows)
```

## F.49.3. Author

Tatsuo Ishii

## F.50. pg\_stat\_statements

The `pg_stat_statements` module provides a means for tracking planning and execution statistics of all SQL statements executed by a server.

The module must be loaded by adding `pg_stat_statements` to `shared_preload_libraries` in `postgresql.conf`, because it requires additional shared memory. This means that a server restart is needed to add or remove the module. In addition, query identifier calculation must be enabled in order for the module to be active, which is done automatically if `compute_query_id` is set to `auto` or `on`, or any third-party module that calculates query identifiers is loaded.

When `pg_stat_statements` is active, it tracks statistics across all databases of the server. To access and manipulate these statistics, the module provides views `pg_stat_statements` and `pg_stat_statements_info`, and the utility functions `pg_stat_statements_reset` and `pg_stat_statements`. These are not available globally but can be enabled for a specific database with `CREATE EXTENSION pg_stat_statements`.

## F.50.1. The `pg_stat_statements` View

The statistics gathered by the module are made available via a view named `pg_stat_statements`. This view contains one row for each distinct combination of database ID, user ID, query ID and whether it's a top-level statement or not (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in [Table F.38](#).

**Table F.38. `pg_stat_statements` Columns**

| Column Type                                                       | Description                                                                                                                                                        |
|-------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>userid oid</code> (references <code>pg_authid .oid</code> ) | OID of user who executed the statement                                                                                                                             |
| <code>dbid oid</code> (references <code>pg_database .oid</code> ) | OID of database in which the statement was executed                                                                                                                |
| <code>toplevel bool</code>                                        | True if the query was executed as a top-level statement (always true if <code>pg_stat_statements.track</code> is set to <code>top</code> )                         |
| <code>queryid bigint</code>                                       | Hash code to identify identical normalized queries.                                                                                                                |
| <code>query text</code>                                           | Text of a representative statement                                                                                                                                 |
| <code>plans bigint</code>                                         | Number of times the statement was planned (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)                                           |
| <code>total_plan_time double precision</code>                     | Total time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)                            |
| <code>min_plan_time double precision</code>                       | Minimum time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)                          |
| <code>max_plan_time double precision</code>                       | Maximum time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)                          |
| <code>mean_plan_time double precision</code>                      | Mean time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)                             |
| <code>stddev_plan_time double precision</code>                    | Population standard deviation of time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero) |
| <code>calls bigint</code>                                         | Number of times the statement was executed                                                                                                                         |
| <code>total_exec_time double precision</code>                     | Total time spent executing the statement, in milliseconds                                                                                                          |
| <code>min_exec_time double precision</code>                       | Minimum time spent executing the statement, in milliseconds                                                                                                        |

| Column Type                       | Description                                                                                                                    |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| max_exec_time double precision    | Maximum time spent executing the statement, in milliseconds                                                                    |
| mean_exec_time double precision   | Mean time spent executing the statement, in milliseconds                                                                       |
| stddev_exec_time double precision | Population standard deviation of time spent executing the statement, in milliseconds                                           |
| rows bigint                       | Total number of rows retrieved or affected by the statement                                                                    |
| shared_blks_hit bigint            | Total number of shared block cache hits by the statement                                                                       |
| shared_blks_read bigint           | Total number of shared blocks read by the statement                                                                            |
| shared_blks_dirtied bigint        | Total number of shared blocks dirtied by the statement                                                                         |
| shared_blks_written bigint        | Total number of shared blocks written by the statement                                                                         |
| local_blks_hit bigint             | Total number of local block cache hits by the statement                                                                        |
| local_blks_read bigint            | Total number of local blocks read by the statement                                                                             |
| local_blks_dirtied bigint         | Total number of local blocks dirtied by the statement                                                                          |
| local_blks_written bigint         | Total number of local blocks written by the statement                                                                          |
| temp_blks_read bigint             | Total number of temp blocks read by the statement                                                                              |
| temp_blks_written bigint          | Total number of temp blocks written by the statement                                                                           |
| blk_read_time double precision    | Total time the statement spent reading blocks, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero) |
| blk_write_time double precision   | Total time the statement spent writing blocks, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero) |
| wal_records bigint                | Total number of WAL records generated by the statement                                                                         |
| wal_fpi bigint                    | Total number of WAL full page images generated by the statement                                                                |
| wal_bytes numeric                 | Total amount of WAL generated by the statement in bytes                                                                        |

For security reasons, only superusers and members of the `pg_read_all_stats` role are allowed to see the SQL text and `queryid` of queries executed by other users. Other users can see the statistics, however, if the view has been installed in their database.

Plannable queries (that is, `SELECT`, `INSERT`, `UPDATE`, and `DELETE`) are combined into a single `pg_stat_statements` entry whenever they have identical query structures according to an internal hash calculation. Typically, two queries will be considered the same for this purpose if they are semantically equiva-

lent except for the values of literal constants appearing in the query. Utility commands (that is, all other commands) are compared strictly on the basis of their textual query strings, however.

### Note

The following details about constant replacement and `queryid` only apply when `compute_query_id` is enabled. If you use an external module instead to compute `queryid`, you should refer to its documentation for details.

When a constant's value has been ignored for purposes of matching the query to other queries, the constant is replaced by a parameter symbol, such as `$1`, in the `pg_stat_statements` display. The rest of the query text is that of the first query that had the particular `queryid` hash value associated with the `pg_stat_statements` entry.

In some cases, queries with visibly different texts might get merged into a single `pg_stat_statements` entry. Normally this will happen only for semantically equivalent queries, but there is a small chance of hash collisions causing unrelated queries to be merged into one entry. (This cannot happen for queries belonging to different users or databases, however.)

Since the `queryid` hash value is computed on the post-parse-analysis representation of the queries, the opposite is also possible: queries with identical texts might appear as separate entries, if they have different meanings as a result of factors such as different `search_path` settings.

Consumers of `pg_stat_statements` may wish to use `queryid` (perhaps in combination with `dbid` and `userid`) as a more stable and reliable identifier for each entry than its query text. However, it is important to understand that there are only limited guarantees around the stability of the `queryid` hash value. Since the identifier is derived from the post-parse-analysis tree, its value is a function of, among other things, the internal object identifiers appearing in this representation. This has some counterintuitive implications. For example, `pg_stat_statements` will consider two apparently-identical queries to be distinct, if they reference a table that was dropped and recreated between the executions of the two queries. The hashing process is also sensitive to differences in machine architecture and other facets of the platform. Furthermore, it is not safe to assume that `queryid` will be stable across major versions of Postgres Pro.

Two servers participating in replication based on physical WAL replay can be expected to have identical `queryid` values for the same query. However, logical replication schemes do not promise to keep replicas identical in all relevant details, so `queryid` will not be a useful identifier for accumulating costs across a set of logical replicas. If in doubt, direct testing is recommended.

Generally, it can be assumed that `queryid` values are stable between minor version releases of PostgreSQL, providing that instances are running on the same machine architecture and the catalog meta-data details match. Compatibility will only be broken between minor versions as a last resort.

The parameter symbols used to replace constants in representative query texts start from the next number after the highest `$n` parameter in the original query text, or `$1` if there was none. It's worth noting that in some cases there may be hidden parameter symbols that affect this numbering. For example, PL/pgSQL uses hidden parameter symbols to insert values of function local variables into queries, so that a PL/pgSQL statement like `SELECT i + 1 INTO j` would have representative text like `SELECT i + $2`.

The representative query texts are kept in an external disk file, and do not consume shared memory. Therefore, even very lengthy query texts can be stored successfully. However, if many long query texts are accumulated, the external file might grow unmanageably large. As a recovery method if that happens, `pg_stat_statements` may choose to discard the query texts, whereupon all existing entries in the `pg_stat_statements` view will show null `query` fields, though the statistics associated with each `queryid` are preserved. If this happens, consider reducing `pg_stat_statements.max` to prevent recurrences.

`plans` and `calls` aren't always expected to match because planning and execution statistics are updated at their respective end phase, and only for successful operations. For example, if a statement is success-

fully planned but fails during the execution phase, only its planning statistics will be updated. If planning is skipped because a cached plan is used, only its execution statistics will be updated.

## F.50.2. The `pg_stat_statements_info` View

The statistics of the `pg_stat_statements` module itself are tracked and made available via a view named `pg_stat_statements_info`. This view contains only a single row. The columns of the view are shown in [Table F.39](#).

**Table F.39. `pg_stat_statements_info` Columns**

| Column Type                                       | Description                                                                                                                                                                                                |
|---------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dealloc bigint</code>                       | Total number of times <code>pg_stat_statements</code> entries about the least-executed statements were deallocated because more distinct statements than <code>pg_stat_statements.max</code> were observed |
| <code>stats_reset timestamp with time zone</code> | Time at which all statistics in the <code>pg_stat_statements</code> view were last reset.                                                                                                                  |

## F.50.3. Functions

`pg_stat_statements_reset(userid Oid, dbid Oid, queryid bigint)` returns void

`pg_stat_statements_reset` discards statistics gathered so far by `pg_stat_statements` corresponding to the specified `userid`, `dbid` and `queryid`. If any of the parameters are not specified, the default value 0 (invalid) is used for each of them and the statistics that match with other parameters will be reset. If no parameter is specified or all the specified parameters are 0 (invalid), it will discard all statistics. If all statistics in the `pg_stat_statements` view are discarded, it will also reset the statistics in the `pg_stat_statements_info` view. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

`pg_stat_statements(showtext boolean)` returns setof record

The `pg_stat_statements` view is defined in terms of a function also named `pg_stat_statements`. It is possible for clients to call the `pg_stat_statements` function directly, and by specifying `showtext := false` have query text be omitted (that is, the `OUT` argument that corresponds to the view's `query` column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all `pg_stat_statements` itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the `pg_stat_statements` data.

## F.50.4. Configuration Parameters

`pg_stat_statements.max (integer)`

`pg_stat_statements.max` is the maximum number of statements tracked by the module (i.e., the maximum number of rows in the `pg_stat_statements` view). If more distinct statements than that are observed, information about the least-executed statements is discarded. The number of times such information was discarded can be seen in the `pg_stat_statements_info` view. The default value is 5000. This parameter can only be set at server start.

`pg_stat_statements.track (enum)`

`pg_stat_statements.track` controls which statements are counted by the module. Specify `top` to track top-level statements (those issued directly by clients), `all` to also track nested statements (such as statements invoked within functions), or `none` to disable statement statistics collection. The default value is `top`. Only superusers can change this setting.

`pg_stat_statements.track_utility` (boolean)

`pg_stat_statements.track_utility` controls whether utility commands are tracked by the module. Utility commands are all those other than `SELECT`, `INSERT`, `UPDATE` and `DELETE`. The default value is `on`. Only superusers can change this setting.

`pg_stat_statements.track_planning` (boolean)

`pg_stat_statements.track_planning` controls whether planning operations and duration are tracked by the module. Enabling this parameter may incur a noticeable performance penalty, especially when statements with identical query structure are executed by many concurrent connections which compete to update a small number of `pg_stat_statements` entries. The default value is `off`. Only superusers can change this setting.

`pg_stat_statements.save` (boolean)

`pg_stat_statements.save` specifies whether to save statement statistics across server shutdowns. If it is `off` then statistics are not saved at shutdown nor reloaded at server start. The default value is `on`. This parameter can only be set in the `postgresql.conf` file or on the server command line.

The module requires additional shared memory proportional to `pg_stat_statements.max`. Note that this memory is consumed whenever the module is loaded, even if `pg_stat_statements.track` is set to `none`.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'pg_stat_statements'

compute_query_id = on
pg_stat_statements.max = 10000
pg_stat_statements.track = all
```

## F.50.5. Sample Output

```
bench=# SELECT pg_stat_statements_reset();

$ pgbench -i bench
$ pgbench -c10 -t300 bench

bench=# \x
bench=# SELECT query, calls, total_exec_time, rows, 100.0 * shared_blks_hit /
           nullif(shared_blks_hit + shared_blks_read, 0) AS hit_percent
           FROM pg_stat_statements ORDER BY total_exec_time DESC LIMIT 5;
-[ RECORD 1 ]-----+-----

### F.50.6. Authors

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>. Query normalization added by Peter Geoghegan <peter@2ndquadrant.com>.

## F.51. pgstattuple

The `pgstattuple` module provides various functions to obtain tuple-level statistics.

Because these functions return detailed page-level information, access is restricted by default. By default, only the role `pg_stat_scan_tables` has `EXECUTE` privilege. Superusers of course bypass this restriction. After the extension has been installed, users may issue `GRANT` commands to change the privileges on the functions to allow others to execute them. However, it might be preferable to add those users to the `pg_stat_scan_tables` role instead.

### F.51.1. Functions

`pgstattuple(regclass)` returns record

`pgstattuple` returns a relation's physical length, percentage of “dead” tuples, and other info. This may help users to determine whether vacuum is necessary or not. The argument is the target relation's name (optionally schema-qualified) or OID. For example:

```

test=> SELECT * FROM pgstattuple('pg_catalog.pg_proc');
-[ RECORD 1 ]-----+-----
table_len      | 458752
tuple_count    | 1470
tuple_len      | 438896
tuple_percent  | 95.67
dead_tuple_count | 11
dead_tuple_len | 3157
dead_tuple_percent | 0.69
free_space     | 8932
free_percent   | 1.95

```

The output columns are described in [Table F.40](#).

**Table F.40. `pgstattuple` Output Columns**

| Column                   | Type                | Description                       |
|--------------------------|---------------------|-----------------------------------|
| <code>table_len</code>   | <code>bigint</code> | Physical relation length in bytes |
| <code>tuple_count</code> | <code>bigint</code> | Number of live tuples             |

Additional Supplied Modules  
and Extensions Shipped in  
postgrespro-ent-14-contrib

| Column             | Type   | Description                          |
|--------------------|--------|--------------------------------------|
| tuple_len          | bigint | Total length of live tuples in bytes |
| tuple_percent      | float8 | Percentage of live tuples            |
| dead_tuple_count   | bigint | Number of dead tuples                |
| dead_tuple_len     | bigint | Total length of dead tuples in bytes |
| dead_tuple_percent | float8 | Percentage of dead tuples            |
| free_space         | bigint | Total free space in bytes            |
| free_percent       | float8 | Percentage of free space             |

### Note

The `table_len` will always be greater than the sum of the `tuple_len`, `dead_tuple_len` and `free_space`. The difference is accounted for by fixed page overhead, the per-page table of pointers to tuples, and padding to ensure that tuples are correctly aligned.

`pgstattuple` acquires only a read lock on the relation. So the results do not reflect an instantaneous snapshot; concurrent updates will affect them.

`pgstattuple` judges a tuple is “dead” if `HeapTupleSatisfiesDirty` returns false.

`pgstattuple(text)` returns record

This is the same as `pgstattuple(regclass)`, except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatindex(regclass)` returns record

`pgstatindex` returns a record showing information about a B-tree index. For example:

```
test=> SELECT * FROM pgstatindex('pg_cast_oid_index');
-[ RECORD 1 ]-----+-----
version          | 2
tree_level       | 0
index_size       | 16384
root_block_no    | 1
internal_pages   | 0
leaf_pages       | 1
empty_pages      | 0
deleted_pages    | 0
avg_leaf_density | 54.27
leaf_fragmentation | 0
```

The output columns are:

| Column         | Type    | Description                              |
|----------------|---------|------------------------------------------|
| version        | integer | B-tree version number                    |
| tree_level     | integer | Tree level of the root page              |
| index_size     | bigint  | Total index size in bytes                |
| root_block_no  | bigint  | Location of root page (zero if none)     |
| internal_pages | bigint  | Number of “internal” (upper-level) pages |

Additional Supplied Modules  
and Extensions Shipped in  
postgrespro-ent-14-contrib

| Column             | Type   | Description                   |
|--------------------|--------|-------------------------------|
| leaf_pages         | bigint | Number of leaf pages          |
| empty_pages        | bigint | Number of empty pages         |
| deleted_pages      | bigint | Number of deleted pages       |
| avg_leaf_density   | float8 | Average density of leaf pages |
| leaf_fragmentation | float8 | Leaf page fragmentation       |

The reported `index_size` will normally correspond to one more page than is accounted for by `internal_pages` + `leaf_pages` + `empty_pages` + `deleted_pages`, because it also includes the index's metapage.

As with `pgstattuple`, the results are accumulated page-by-page, and should not be expected to represent an instantaneous snapshot of the whole index.

`pgstatindex(text)` returns record

This is the same as `pgstatindex(regclass)`, except that the target index is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatginindex(regclass)` returns record

`pgstatginindex` returns a record showing information about a GIN index. For example:

```
test=> SELECT * FROM pgstatginindex('test_gin_index');
-[ RECORD 1 ]--+-
version          | 1
pending_pages    | 0
pending_tuples   | 0
```

The output columns are:

| Column         | Type    | Description                          |
|----------------|---------|--------------------------------------|
| version        | integer | GIN version number                   |
| pending_pages  | integer | Number of pages in the pending list  |
| pending_tuples | bigint  | Number of tuples in the pending list |

`pgstathashindex(regclass)` returns record

`pgstathashindex` returns a record showing information about a HASH index. For example:

```
test=> select * from pgstathashindex('con_hash_index');
-[ RECORD 1 ]--+-
version          | 4
bucket_pages     | 33081
overflow_pages   | 0
bitmap_pages     | 1
unused_pages     | 32455
live_items       | 10204006
dead_items       | 0
free_percent     | 61.8005949100872
```

The output columns are:

| Column  | Type    | Description         |
|---------|---------|---------------------|
| version | integer | HASH version number |

Additional Supplied Modules  
and Extensions Shipped in  
postgrespro-ent-14-contrib

| Column         | Type   | Description              |
|----------------|--------|--------------------------|
| bucket_pages   | bigint | Number of bucket pages   |
| overflow_pages | bigint | Number of overflow pages |
| bitmap_pages   | bigint | Number of bitmap pages   |
| unused_pages   | bigint | Number of unused pages   |
| live_items     | bigint | Number of live tuples    |
| dead_tuples    | bigint | Number of dead tuples    |
| free_percent   | float  | Percentage of free space |

`pg_relpages(regclass)` returns `bigint`

`pg_relpages` returns the number of pages in the relation.

`pg_relpages(text)` returns `bigint`

This is the same as `pg_relpages(regclass)`, except that the target relation is specified as `TEXT`. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstattuple_approx(regclass)` returns `record`

`pgstattuple_approx` is a faster alternative to `pgstattuple` that returns approximate results. The argument is the target relation's name or OID. For example:

```
test=> SELECT * FROM pgstattuple_approx('pg_catalog.pg_proc'::regclass);
-[ RECORD 1 ]-----+-----
table_len          | 573440
scanned_percent    | 2
approx_tuple_count | 2740
approx_tuple_len   | 561210
approx_tuple_percent | 97.87
dead_tuple_count   | 0
dead_tuple_len     | 0
dead_tuple_percent | 0
approx_free_space  | 11996
approx_free_percent | 2.09
```

The output columns are described in [Table F.41](#).

Whereas `pgstattuple` always performs a full-table scan and returns an exact count of live and dead tuples (and their sizes) and free space, `pgstattuple_approx` tries to avoid the full-table scan and returns exact dead tuple statistics along with an approximation of the number and size of live tuples and free space.

It does this by skipping pages that have only visible tuples according to the visibility map (if a page has the corresponding VM bit set, then it is assumed to contain no dead tuples). For such pages, it derives the free space value from the free space map, and assumes that the rest of the space on the page is taken up by live tuples.

For pages that cannot be skipped, it scans each tuple, recording its presence and size in the appropriate counters, and adding up the free space on the page. At the end, it estimates the total number of live tuples based on the number of pages and tuples scanned (in the same way that `VACUUM` estimates `pg_class.reltuples`).

**Table F.41. `pgstattuple_approx` Output Columns**

| Column    | Type   | Description                               |
|-----------|--------|-------------------------------------------|
| table_len | bigint | Physical relation length in bytes (exact) |

Additional Supplied Modules  
and Extensions Shipped in  
postgrespro-ent-14-contrib

| Column               | Type   | Description                                      |
|----------------------|--------|--------------------------------------------------|
| scanned_percent      | float8 | Percentage of table scanned                      |
| approx_tuple_count   | bigint | Number of live tuples (estimated)                |
| approx_tuple_len     | bigint | Total length of live tuples in bytes (estimated) |
| approx_tuple_percent | float8 | Percentage of live tuples                        |
| dead_tuple_count     | bigint | Number of dead tuples (exact)                    |
| dead_tuple_len       | bigint | Total length of dead tuples in bytes (exact)     |
| dead_tuple_percent   | float8 | Percentage of dead tuples                        |
| approx_free_space    | bigint | Total free space in bytes (estimated)            |
| approx_free_percent  | float8 | Percentage of free space                         |

In the above output, the free space figures may not match the `pgstattuple` output exactly, because the free space map gives us an exact figure, but is not guaranteed to be accurate to the byte.

## F.51.2. Authors

Tatsuo Ishii, Satoshi Nagayasu and Abhijit Menon-Sen

## F.52. pg\_surgery

The `pg_surgery` module provides various functions to perform surgery on a damaged relation. These functions are unsafe by design and using them may corrupt (or further corrupt) your database. For example, these functions can easily be used to make a table inconsistent with its own indexes, to cause `UNIQUE` or `FOREIGN KEY` constraint violations, or even to make tuples visible which, when read, will cause a database server crash. They should be used with great caution and only as a last resort.

### F.52.1. Functions

`heap_force_kill(regclass, tid[])` returns void

`heap_force_kill` marks “used” line pointers as “dead” without examining the tuples. The intended use of this function is to forcibly remove tuples that are not otherwise accessible. For example:

```
test=> select * from t1 where ctid = '(0, 1)';
ERROR:  could not access status of transaction 4007513275
DETAIL:  Could not open file "pg_xact/0EED": No such file or directory.
```

```
test=# select heap_force_kill('t1'::regclass, ARRAY['(0, 1)']::tid[]);
 heap_force_kill
-----
```

```
(1 row)
```

```
test=# select * from t1 where ctid = '(0, 1)';
(0 rows)
```

`heap_force_freeze(regclass, tid[])` returns void

`heap_force_freeze` marks tuples as frozen without examining the tuple data. The intended use of this function is to make accessible tuples which are inaccessible due to corrupted visibility information, or which prevent the table from being successfully vacuumed due to corrupted visibility information. For example:

```
test=> vacuum t1;
ERROR:  found xmin 507 from before relfrozenxid 515
CONTEXT:  while scanning block 0 of relation "public.t1"

test=# select ctid from t1 where xmin = 507;
 ctid
-----
(0,3)
(1 row)

test=# select heap_force_freeze('t1'::regclass, ARRAY['(0, 3)']::tid[]);
 heap_force_freeze
-----

(1 row)

test=# select ctid from t1 where xmin = 2;
 ctid
-----
(0,3)
(1 row)
```

## F.52.2. Authors

Ashutosh Sharma <ashu.coek88@gmail.com>

## F.53. pg\_transfer

The `pg_transfer` extension enables quick transfer of tables between Postgres Pro Enterprise instances.

It may sometimes be required to load large volumes of data into a database, for example, when consolidating data from regional servers into a central one. If your data needs to be uploaded to a server under heavy load, you can use a temporary database on another server to accumulate the data and then transfer it all at once when the main server load is minimal.

If you use `pg_dump` and `pg_restore` applications to transfer data, the load on the receiving server is usually higher than that on the sending server. Since the data is loaded using `INSERT` or `COPY` commands, it creates a significant impact on the disk subsystem. Besides, you will have to re-build indexes in the target database once all the data is loaded, which will also contribute to the server load.

To achieve a much higher load speed for read-only data, you can use the `pg_transfer` extension while doing dump/restore, which allows to copy data files directly, without using `COPY/INSERT` commands. `pg_transfer` also provides auxiliary functions for `pg_dump` and `pg_restore` to transfer tables together with pre-built indexes and collected statistics, so you can avoid extra load on the target server incurred by statistics re-collection.

### Note

Postgres Pro Enterprise configuration and the architectures of source and target servers must provide binary-compatible file formats. When restoring data, `pg_transfer` checks that source and target servers have the same alignment, page and segment sizes, etc.

## F.53.1. Installation

`pg_transfer` is included into Postgres Pro Enterprise. To enable `pg_transfer`, create its extension in your database using the following SQL command:

```
CREATE EXTENSION pg_transfer;
```

You must create `pg_transfer` extension in both source and target databases.

## F.53.2. Usage

To transfer data using the `pg_transfer` module, do the following:

### 1. Prepare source and target systems for data transfer

Before the actual data transfer, you first need to transfer data schema to the target server:

1. In the source database, mark the table to be transferred as read-only:

```
ALTER TABLE table_name SET CONSTANT;
```

2. Run the `VACUUM (ANALYZE)` command to remove dead tuples and refresh statistics:

```
VACUUM (ANALYZE) table_name;
```

3. Take a logical dump of the data schema on the source server and restore it on the target server:

```
pg_dump -Fc -t table_name --schema-only -f transfer_dir/archive.out old_database  
pg_restore -d new_database --schema-only transfer_dir/archive.out
```

### 2. Prepare TOAST identifiers for the transfer

This step is only required if the tables to be transferred have toasted values.

1. Determine TOAST identifiers (*reltoastid*) in the new database:

```
psql new_database -c "SELECT reltoastrelid FROM pg_class WHERE  
relname='table_name';"
```

2. Using the received *reltoastid* identifiers, prepare the table for the transfer and force data flush to disk:

```
psql -d old_database -c "SELECT  
pg_transfer_freeze('table_name::regclass::oid, reltoastrelid::oid);"
```

### 3. Transfer the data to the target system

1. Copy the data into a separate directory using `pg_dump` utility:

```
pg_dump -Fc -t table_name --transfer-dir transfer_dir/ -f transfer_dir/  
archive.out old_database
```

2. Restore the data in the target database:

```
pg_restore -d new_database --data-only --transfer-dir transfer_dir/ --copy-mode=  
transfer transfer_dir/archive.out
```

When source and target databases are located in the same file system, the `--copy-mode=transfer` option must be specified at least once (for either `pg_dump` or `pg_restore` command) to get an independent copy of data. When restoring data on the primary server, `--generate-wal` option must be specified for `pg_restore` for changes to be replicated to a standby server.

## F.53.3. Compatibility

The `pg_transfer` extension is only supported on Linux systems.

## F.53.4. Authors

Postgres Professional, Moscow, Russia

## F.54. pg\_trgm

The `pg_trgm` module provides functions and operators for determining the similarity of alphanumeric text based on trigram matching, as well as index operator classes that support fast searching for similar strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

## F.54.1. Trigram (or Trigraph) Concepts

A trigram is a group of three consecutive characters taken from a string. We can measure the similarity of two strings by counting the number of trigrams they share. This simple idea turns out to be very effective for measuring the similarity of words in many natural languages.

### Note

`pg_trgm` ignores non-word characters (non-alphanumerics) when extracting trigrams from a string. Each word is considered to have two spaces prefixed and one space suffixed when determining the set of trigrams contained in the string. For example, the set of trigrams in the string “cat” is “ c”, “ ca”, “cat”, and “at ”. The set of trigrams in the string “foo|bar” is “ f”, “ fo”, “foo”, “oo ”, “ b”, “ ba”, “bar”, and “ar ”.

## F.54.2. Functions and Operators

The functions provided by the `pg_trgm` module are shown in [Table F.42](#), the operators in [Table F.43](#).

**Table F.42. `pg_trgm` Functions**

| Function                                                  | Description                                                                                                                                                                                                                                                                                                  |
|-----------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>similarity ( text, text ) → real</code>             | Returns a number that indicates how similar the two arguments are. The range of the result is zero (indicating that the two strings are completely dissimilar) to one (indicating that the two strings are identical).                                                                                       |
| <code>show_trgm ( text ) → text[]</code>                  | Returns an array of all the trigrams in the given string. (In practice this is seldom useful except for debugging.)                                                                                                                                                                                          |
| <code>word_similarity ( text, text ) → real</code>        | Returns a number that indicates the greatest similarity between the set of trigrams in the first string and any continuous extent of an ordered set of trigrams in the second string. For details, see the explanation below.                                                                                |
| <code>strict_word_similarity ( text, text ) → real</code> | Same as <code>word_similarity</code> , but forces extent boundaries to match word boundaries. Since we don't have cross-word trigrams, this function actually returns greatest similarity between first string and any continuous extent of words of the second string.                                      |
| <code>show_limit () → real</code>                         | Returns the current similarity threshold used by the <code>%</code> operator. This sets the minimum similarity between two words for them to be considered similar enough to be misspellings of each other, for example. ( <i>Deprecated</i> ; instead use <code>SHOW pg_trgm.similarity_threshold</code> .) |
| <code>set_limit ( real ) → real</code>                    | Sets the current similarity threshold that is used by the <code>%</code> operator. The threshold must be between 0 and 1 (default is 0.3). Returns the same value passed in. ( <i>Deprecated</i> ; instead use <code>SET pg_trgm.similarity_threshold</code> .)                                              |

Consider the following example:

```
# SELECT word_similarity('word', 'two words');
word_similarity
-----
```

0.8

(1 row)

In the first string, the set of trigrams is {" w", " wo", "wor", "ord", "rd "}. In the second string, the ordered set of trigrams is {" t", " tw", "two", "wo ", " w", " wo", "wor", "ord", "rds", "ds "}. The most similar extent of an ordered set of trigrams in the second string is {" w", " wo", "wor", "ord"}, and the similarity is 0.8.

This function returns a value that can be approximately understood as the greatest similarity between the first string and any substring of the second string. However, this function does not add padding to the boundaries of the extent. Thus, the number of additional characters present in the second string is not considered, except for the mismatched word boundaries.

At the same time, `strict_word_similarity` selects an extent of words in the second string. In the example above, `strict_word_similarity` would select the extent of a single word 'words', whose set of trigrams is {" w", " wo", "wor", "ord", "rds", "ds "}.

```
# SELECT strict_word_similarity('word', 'two words'), similarity('word', 'words');
strict_word_similarity | similarity
-----+-----
0.571429 | 0.571429
(1 row)
```

Thus, the `strict_word_similarity` function is useful for finding the similarity to whole words, while `word_similarity` is more suitable for finding the similarity for parts of words.

**Table F.43. pg\_trgm Operators**

| Operator                                        | Description                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>text % text → boolean</code>              | Returns <code>true</code> if its arguments have a similarity that is greater than the current similarity threshold set by <code>pg_trgm.similarity_threshold</code> .                                                                                                                                                                 |
| <code>text &lt;% text → boolean</code>          | Returns <code>true</code> if the similarity between the trigram set in the first argument and a continuous extent of an ordered trigram set in the second argument is greater than the current word similarity threshold set by <code>pg_trgm.word_similarity_threshold</code> parameter.                                             |
| <code>text %&gt; text → boolean</code>          | Commutator of the <code>&lt;%</code> operator.                                                                                                                                                                                                                                                                                        |
| <code>text &lt;&lt;% text → boolean</code>      | Returns <code>true</code> if its second argument has a continuous extent of an ordered trigram set that matches word boundaries, and its similarity to the trigram set of the first argument is greater than the current strict word similarity threshold set by the <code>pg_trgm.strict_word_similarity_threshold</code> parameter. |
| <code>text %&gt;&gt; text → boolean</code>      | Commutator of the <code>&lt;&lt;%</code> operator.                                                                                                                                                                                                                                                                                    |
| <code>text &lt;-&gt; text → real</code>         | Returns the “distance” between the arguments, that is one minus the <code>similarity()</code> value.                                                                                                                                                                                                                                  |
| <code>text &lt;&lt;-&gt; text → real</code>     | Returns the “distance” between the arguments, that is one minus the <code>word_similarity()</code> value.                                                                                                                                                                                                                             |
| <code>text &lt;-&gt;&gt; text → real</code>     | Commutator of the <code>&lt;&lt;-&gt;</code> operator.                                                                                                                                                                                                                                                                                |
| <code>text &lt;&lt;&lt;-&gt; text → real</code> |                                                                                                                                                                                                                                                                                                                                       |

| Operator                                        | Description                                                                                                      |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
|                                                 | Returns the “distance” between the arguments, that is one minus the <code>strict_word_similarity()</code> value. |
| <code>text &lt;-&gt;&gt;&gt; text → real</code> | Commutator of the <code>&lt;&lt;&lt;-&gt;</code> operator.                                                       |

### F.54.3. GUC Parameters

`pg_trgm.similarity_threshold (real)`

Sets the current similarity threshold that is used by the `%` operator. The threshold must be between 0 and 1 (default is 0.3).

`pg_trgm.word_similarity_threshold (real)`

Sets the current word similarity threshold that is used by the `<%` and `%>` operators. The threshold must be between 0 and 1 (default is 0.6).

`pg_trgm.strict_word_similarity_threshold (real)`

Sets the current strict word similarity threshold that is used by the `<<%` and `%>>` operators. The threshold must be between 0 and 1 (default is 0.5).

### F.54.4. Index Support

The `pg_trgm` module provides GiST and GIN index operator classes that allow you to create an index over a text column for the purpose of very fast similarity searches. These index types support the above-described similarity operators, and additionally support trigram-based index searches for `LIKE`, `ILIKE`, `~`, `~*` and `=` queries. Inequality operators are not supported. Note that those indexes may not be as efficient as regular B-tree indexes for equality operator.

Example:

```
CREATE TABLE test_trgm (t text);
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops);
```

or

```
CREATE INDEX trgm_idx ON test_trgm USING GIN (t gin_trgm_ops);
```

`gist_trgm_ops` GiST opclass approximates a set of trigrams as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default length is 12 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

```
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops(siglen=32));
```

At this point, you will have an index on the `t` column that you can use for similarity searching. A typical query is

```
SELECT t, similarity(t, 'word') AS sml
FROM test_trgm
WHERE t % 'word'
ORDER BY sml DESC, t;
```

This will return all values in the text column that are sufficiently similar to `word`, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

A variant of the above query is

```
SELECT t, t <-> 'word' AS dist
FROM test_trgm
```

```
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes. It will usually beat the first formulation when only a small number of the closest matches is wanted.

Also you can use an index on the `t` column for word similarity or strict word similarity. Typical queries are:

```
SELECT t, word_similarity('word', t) AS sml
FROM test_trgm
WHERE 'word' <% t
ORDER BY sml DESC, t;
```

and

```
SELECT t, strict_word_similarity('word', t) AS sml
FROM test_trgm
WHERE 'word' <<% t
ORDER BY sml DESC, t;
```

This will return all values in the text column for which there is a continuous extent in the corresponding ordered trigram set that is sufficiently similar to the trigram set of *word*, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

Possible variants of the above queries are:

```
SELECT t, 'word' <<-> t AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

and

```
SELECT t, 'word' <<<-> t AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes.

Beginning in PostgreSQL 9.1, these index types also support index searches for `LIKE` and `ILIKE`, for example

```
SELECT * FROM test_trgm WHERE t LIKE '%foo%bar';
```

The index search works by extracting trigrams from the search string and then looking these up in the index. The more trigrams in the search string, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

Beginning in PostgreSQL 9.3, these index types also support index searches for regular-expression matches (`~` and `~*` operators), for example

```
SELECT * FROM test_trgm WHERE t ~ '(foo|bar)';
```

The index search works by extracting trigrams from the regular expression and then looking these up in the index. The more trigrams that can be extracted from the regular expression, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

For both `LIKE` and regular-expression searches, keep in mind that a pattern with no extractable trigrams will degenerate to a full-index scan.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

## F.54.5. Text Search Integration

Trigram matching is a very useful tool when used in conjunction with a full text index. In particular it can help to recognize misspelled input words that will not be matched directly by the full text search mechanism.

The first step is to generate an auxiliary table containing all the unique words in the documents:

```
CREATE TABLE words AS SELECT word FROM
    ts_stat('SELECT to_tsvector(''simple'', bodytext) FROM documents');
```

where `documents` is a table that has a text field `bodytext` that we wish to search. The reason for using the simple configuration with the `to_tsvector` function, instead of using a language-specific configuration, is that we want a list of the original (unstemmed) words.

Next, create a trigram index on the word column:

```
CREATE INDEX words_idx ON words USING GIN (word gin_trgm_ops);
```

Now, a `SELECT` query similar to the previous example can be used to suggest spellings for misspelled words in user search terms. A useful extra test is to require that the selected words are also of similar length to the misspelled word.

### Note

Since the `words` table has been generated as a separate, static table, it will need to be periodically regenerated so that it remains reasonably up-to-date with the document collection. Keeping it exactly current is usually unnecessary.

## F.55. pg\_trgm\_mchar

`pg_trgm_mchar` is a Postgres Pro extension that allows fast trigram-based search for similar `mchar` and `mvarchar` strings. The functionality provided by this extension overlaps substantially with the functionality of `pg_trgm`: it provides equivalent [functions](#) and [operators](#) adjusted for `mchar` and `mvarchar` types. However, `pg_trgm_mchar` supports only the [GIN](#) operator classes for searching these column types.

### Note

The `LIKE` operator supports only `(mchar, mvarchar)` operand types. `(mchar, mchar)` operands are not supported.

### F.55.1. Installation

`pg_trgm_mchar` is a built-in extension included into Postgres Pro Enterprise. It depends on both `pg_trgm` and `mchar`. You must install these modules before creating `pg_trgm_mchar`, or you can install all dependencies automatically with:

```
CREATE EXTENSION pg_trgm_mchar CASCADE;
```

Alternatively, if both required modules are already installed, you can enable `pg_trgm_mchar` using the following query:

```
CREATE EXTENSION pg_trgm_mchar;
```

Since `mchar` and `mvvarchar` data types use the ICU library, it is also required for correct operation of the extension.

## F.55.2. Example

Since `pg_trgm_mchar` operates almost identically to `pg_trgm`, for usage examples, refer to the [pg\\_trgm documentation](#).

However, there is a difference in index creation processes. The `pg_trgm_mchar` extension uses the `gin_trgm_ops_mvvarchar/gin_trgm_ops_mchar` operator family instead of `gin_trgm_ops` used by `pg_trgm`:

```
CREATE TABLE test_trgm(t mvvarchar);
CREATE INDEX trgm_idx ON test_trgm USING gin (t gin_trgm_ops_mvvarchar);
...
CREATE TABLE test_trgm_mchar(t mchar);
CREATE INDEX trgm_mchar_idx ON test_trgm_mchar USING gin (t gin_trgm_ops_mchar);
```

In all other cases, these two modules behave identically.

## F.56. pg\_tsparser

`pg_tsparser` is a Postgres Pro extension for text search. This extension modifies the default text parsing strategy for words that include:

- underscores
- numbers and letters separated by the hyphen character

In addition to separate word parts returned by default, `pg_tsparser` also returns the whole word.

### F.56.1. Installation and Setup

`pg_tsparser` is included into the Postgres Pro distribution. To enable `pg_tsparser`, once Postgres Pro is installed, create the `pg_tsparser` extension for each database you are planning to use:

```
CREATE EXTENSION pg_tsparser;
```

Once `pg_tsparser` is enabled, you can create your own text search configuration. In addition to `pg_tsparser`, you can use any available dictionary.

For example, you can create `english_ts` configuration for the English language, as follows:

```
CREATE TEXT SEARCH CONFIGURATION english_ts (
    PARSER = tsparser
);

COMMENT ON TEXT SEARCH CONFIGURATION english_ts IS 'text search configuration for
english language';

ALTER TEXT SEARCH CONFIGURATION english_ts
    ADD MAPPING FOR email, file, float, host, hword_numpart, int,
    numhword, numword, sfloat, uint, url, url_path, version
    WITH simple;

ALTER TEXT SEARCH CONFIGURATION english_ts
    ADD MAPPING FOR asciiword, asciihword, hword_asciipart,
    word, hword, hword_part
```

```
WITH english_stem;
```

## F.56.2. Examples

The following examples illustrate the difference in search results returned by `pg_tsparser` and the default parser:

```
SELECT to_tsvector('english', 'pg_trgm') as def_parser,  
       to_tsvector('english_ts', 'pg_trgm') as new_parser;  
def_parser | new_parser  
-----+-----  
'pg':1 'trgm':2 | 'pg':2 'pg_trgm':1 'trgm':3  
(1 row)
```

```
SELECT to_tsvector('english', '123-abc') as def_parser,  
       to_tsvector('english_ts', '123-abc') as new_parser;  
def_parser | new_parser  
-----+-----  
'123':1 'abc':2 | '123':2 '123-abc':1 'abc':3  
(1 row)
```

```
SELECT to_tsvector('english', 'rel-3.2-A') as def_parser,  
       to_tsvector('english_ts', 'rel-3.2-A') as new_parser;  
def_parser | new_parser  
-----+-----  
'-3.2':2 'rel':1 | '3.2':3 'rel':2 'rel-3.2-a':1  
(1 row)
```

Postgres Professional, Moscow, Russia

## F.57. pg\_variables

The `pg_variables` module provides functions for working with variables of various types. The created variables are only available in the current user session.

### Note

This extension cannot be used while built-in connection pooling is enabled.

### F.57.1. Installation

The `pg_variables` extension is included into Postgres Pro. Once you have Postgres Pro installed, you must execute the [CREATE EXTENSION](#) command to enable `pg_variables`, as follows:

```
CREATE EXTENSION pg_variables;
```

### F.57.2. Usage

The `pg_variables` module provides several functions for creating, reading, and managing variables of scalar, record, and array types. See the following sections for function descriptions and syntax:

- [Section F.57.3.1](#) describes functions for scalar variables.

- [Section F.57.3.2](#) describes functions for collections of record variables.
- [Section F.57.3.3](#) describes functions for array variables.
- [Section F.57.3.4](#) describes functions for general collection variables.
- [Section F.57.3.5](#) describes functions for using iterators to traverse collection variables.
- [Section F.57.3.6](#) lists functions you can use to manage all variables in your current session.

For detailed usage examples, see [Section F.57.5](#).

### F.57.2.1. Using Transactional Variables

By default, the created variables are non-transactional. Once successfully set, a variable exists for the whole session, regardless of rollbacks, if any. For example:

```
SELECT pgv_set('vars', 'int1', 101);
BEGIN;
SELECT pgv_set('vars', 'int2', 102);
ROLLBACK;
```

```
SELECT * FROM pgv_list() order by package, name;
 package | name | is_transactional
-----+-----+-----
 vars    | int1 | f
 vars    | int2 | f
```

If you would like to use variables that support transactions and savepoints, pass the optional `is_transactional` flag as the last parameter when creating this variable:

```
BEGIN;
SELECT pgv_set('vars', 'trans_int', 101, true);
SAVEPOINT sp1;
SELECT pgv_set('vars', 'trans_int', 102, true);
ROLLBACK TO sp1;
COMMIT;
SELECT pgv_get('vars', 'trans_int', NULL::int);
 pgv_get
-----
      101
```

You must use the `is_transactional` flag every time you change the value of a transactional variable using `pgv_set()` or `pgv_insert()` functions. Otherwise, an error occurs. Other functions do not require this flag.

```
SELECT pgv_insert('pack', 'var_record', row(123::int, 'text'::text), true);

SELECT pgv_insert('pack', 'var_record', row(456::int, 'another text'::text));
ERROR:  variable "var_record" already created as TRANSACTIONAL

SELECT pgv_delete('pack', 'var_record', 123::int);
```

If the `pgv_free()` or `pgv_remove()` function calls are rolled back, the affected transactional variables will be restored, unlike non-transactional variables, which are removed permanently. For example:

```
SELECT pgv_set('pack', 'var_reg', 123);
SELECT pgv_set('pack', 'var_trans', 456, true);
BEGIN;
SELECT pgv_free();
ROLLBACK;
SELECT * FROM pgv_list();
 package | name | is_transactional
-----+-----+-----
```

## F.57.3. Functions

### F.57.3.1. Scalar Variables

The following functions support scalar variables:

| Function                                                                                              | Returns     |
|-------------------------------------------------------------------------------------------------------|-------------|
| <code>pgv_set(package text, name text, value anynonarray, is_transactional bool default false)</code> | void        |
| <code>pgv_get(package text, name text, var_type anynonarray, strict bool default true)</code>         | anynonarray |

To use the `pgv_get()` function, you must first create a package and a variable using the `pgv_set()` function. If the specified package or variable does not exist, an error occurs:

```
SELECT pgv_get('vars', 'int1', NULL::int);
ERROR: unrecognized package "vars"
```

```
SELECT pgv_get('vars', 'int1', NULL::int);
ERROR: unrecognized variable "int1"
```

`pgv_get()` function checks the variable type. If the specified type does not match the type of the variable, an error is raised:

```
SELECT pgv_get('vars', 'int1', NULL::text);
ERROR: variable "int1" requires "integer" value
```

### F.57.3.2. Collections of Records

The following functions support collections of record variables:

| Function                                                                                        | Returns | Description                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------------------------------------------------------------------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pgv_insert(package text, name text, r record, is_transactional bool default false)</code> | void    | Inserts a record into a collection variable for the specified package. If the package or variable does not exist, it is created automatically. The first column of <code>r</code> is the primary key. If a record with the same primary key already exists or this collection variable has a different structure, an error is raised. |
| <code>pgv_update(package text, name text, r record)</code>                                      | boolean | Updates a record with the corresponding primary key (the first column of <code>r</code> is the primary key). Returns <code>true</code> if the record was found. If this collection variable has a different structure, an error is raised.                                                                                            |
| <code>pgv_delete(package text, name text, value anynonarray)</code>                             | boolean | Deletes a record with the corresponding primary key (the first column of <code>r</code> is the primary key). Returns <code>true</code> if the record was found and <code>false</code> otherwise.                                                                                                                                      |

Additional Supplied Modules  
and Extensions Shipped in  
postgrespro-ent-14-contrib

| Function                                                            | Returns        | Description                                                                                                                        |
|---------------------------------------------------------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------|
| <code>pgv_select(package text, name text)</code>                    | set of records | Returns the collection variable records.                                                                                           |
| <code>pgv_select(package text, name text, value anynonarray)</code> | record         | Returns the record with the corresponding primary key (the first column of <code>r</code> is a primary key).                       |
| <code>pgv_select(package text, name text, value anyarray)</code>    | set of records | Returns the collection variable records with the corresponding primary keys (the first column of <code>r</code> is a primary key). |

To use `pgv_update()`, `pgv_delete()` and `pgv_select()` functions, you must first create a package and a variable using the `pgv_insert()` function. The variable type and the record type must be the same; otherwise, an error occurs.

### F.57.3.3. Arrays

The following functions support array variables:

| Function                                                                                           | Returns  |
|----------------------------------------------------------------------------------------------------|----------|
| <code>pgv_set(package text, name text, value anyarray, is_transactional bool default false)</code> | void     |
| <code>pgv_get(package text, name text, var_type anyarray, strict bool default true)</code>         | anyarray |

Usage instructions for these functions are the same as those provided in [Section F.57.3.1](#) for scalar variables.

### F.57.3.4. General Collections

The following functions support general collection variables:

| Function                                                                                                                                                                                                                                      | Returns | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pgv_set_elem(package text, name text, key int, value anyelement, is_transactional bool default false)</code><br><br><code>pgv_set_elem(package text, name text, key text, value anyelement, is_transactional bool default false)</code> | void    | Sets a value for the element with the key <code>key</code> of the collection variable <code>name</code> in the package <code>package</code> . If the package or variable does not exist, it is created automatically. Inside one collection, only keys of the same type are allowed. The <code>key</code> argument can have either <code>int</code> or <code>text</code> type. If an element with the specified key already exists, its value is set to the new one. <code>is_transactional</code> shows whether the new variable is transactional and equals <code>false</code> by default. So if the variable already exists, it must be transactional/non-transactional as indicated by <code>is_transactional</code> , otherwise an error is raised. If the collection already exists and its value type does not |

| Function                                                                                                                                                                         | Returns    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                                                                                                  |            | match the type of the new value, an error is also raised.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <p><code>pgv_get_elem(package text, name text, key int, val_type anyelement)</code></p> <p><code>pgv_get_elem(package text, name text, key text, val_type anyelement)</code></p> | anyelement | Returns the value of the element with the key <code>key</code> of the collection variable <code>name</code> in the package <code>package</code> . If there is no element with the specified key in this collection, returns NULL. The <code>key</code> argument can have either <code>int</code> or <code>text</code> type. If the package or variable does not exist, an error is raised. If the specified variable is not a collection, an error is also raised. The <code>val_type</code> argument is required to properly determine the return type. |
| <p><code>pgv_exists_elem(package text, name text, key int)</code></p> <p><code>pgv_exists_elem(package text, name text, key text)</code></p>                                     | bool       | Returns <code>true</code> if an element with the key <code>key</code> exists in the collection variable <code>name</code> in the package <code>package</code> and <code>false</code> otherwise. If the package or variable does not exist, also returns <code>false</code> . The <code>key</code> argument can have either <code>int</code> or <code>text</code> type. If the specified variable is not a collection, an error is raised.                                                                                                                |
| <p><code>pgv_remove_elem(package text, name text, key int)</code></p> <p><code>pgv_remove_elem(package text, name text, key text)</code></p>                                     | void       | Removes the element with the key <code>key</code> from the collection variable <code>name</code> in the package <code>package</code> . If there is no element with the specified key in this collection, does nothing. The <code>key</code> argument can have either <code>int</code> or <code>text</code> type. If the package or variable does not exist, an error is raised. If the specified variable is not a collection, an error is also raised.                                                                                                  |

### Important

Collections initialized with `pgv_set_elem()` and with `pgv_insert()` are not considered compatible.

#### F.57.3.5. Iterators

The following functions are provided to use iterators to traverse collection variables. These functions work with collections initialized with both `pgv_set_elem()` and `pgv_insert()`.

| Function                                                             | Returns    | Description                                                                                                                                 |
|----------------------------------------------------------------------|------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pgv_first(package text, name text, key_type anyelement)</code> | anyelement | Returns the first key from the collection variable. Collections are sorted by the key in ascending order. <code>key_type</code> is required |

Additional Supplied Modules  
and Extensions Shipped in  
postgrespro-ent-14-contrib

| Function                                                            | Returns                 | Description                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------------------------------------|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                     |                         | to determine the return value. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.                                                                                                                                                                                                      |
| <code>pgv_last(package text, name text, key_type anyelement)</code> | <code>anyelement</code> | Returns the last key from the collection variable. Collections are sorted by the key in ascending order. <code>key_type</code> is required to determine the return value. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.                                                           |
| <code>pgv_next(package text, name text, key anyelement)</code>      | <code>anyelement</code> | Returns the next key from the collection variable. The <code>key</code> passed may not exist in the collection. Returns NULL if used for the last key in the collection. Collections are sorted by the key in ascending order. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.      |
| <code>pgv_prior(package text, name text, key anyelement)</code>     | <code>anyelement</code> | Returns the previous key from the collection variable. The <code>key</code> passed may not exist in the collection. Returns NULL if used for the first key in the collection. Collections are sorted by the key in ascending order. If the <code>name</code> passed is the name of a non-collection variable, an error is raised. |
| <code>pgv_count(package text, name text)</code>                     | <code>integer</code>    | Returns the number of elements in the collection. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.                                                                                                                                                                                   |

### F.57.3.6. Miscellaneous Functions

| Function                                         | Returns           | Description                                                                                                                 |
|--------------------------------------------------|-------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <code>pgv_exists(package text, name text)</code> | <code>bool</code> | Returns <code>true</code> if the specified package and variable exist and <code>false</code> otherwise.                     |
| <code>pgv_exists(package text)</code>            | <code>bool</code> | Returns <code>true</code> if the specified package exists and <code>false</code> otherwise.                                 |
| <code>pgv_remove(package text, name text)</code> | <code>void</code> | Removes the variable with the specified name. The specified package and variable must exist; otherwise, an error is raised. |
| <code>pgv_remove(package text)</code>            | <code>void</code> | Removes the specified package and all the corresponding vari-                                                               |

| Function                 | Returns                                                            | Description                                                                                                                                                                                                                                                                                        |
|--------------------------|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                                                                    | ables. The specified package must exist; otherwise, an error is raised.                                                                                                                                                                                                                            |
| <code>pgv_free()</code>  | <code>void</code>                                                  | Removes all packages and variables.                                                                                                                                                                                                                                                                |
| <code>pgv_list()</code>  | <code>table(package text, name text, is_transactional bool)</code> | Displays all the available variables and the corresponding packages, as well as whether each variable is transactional.                                                                                                                                                                            |
| <code>pgv_stats()</code> | <code>table(package text, allocated_memory bigint)</code>          | Returns the list of assigned packages and the amount of memory used by variables, in bytes. If you are using transactional variables, this list also includes all deleted packages that still may be restored by a <code>ROLLBACK</code> . This function only supports Postgres Pro 9.6 or higher. |

### F.57.3.7. Deprecated Functions

#### F.57.3.7.1. Integer Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

| Function                                                                                          | Returns           |
|---------------------------------------------------------------------------------------------------|-------------------|
| <code>pgv_set_int(package text, name text, value int, is_transactional bool default false)</code> | <code>void</code> |
| <code>pgv_get_int(package text, name text, strict bool default true)</code>                       | <code>int</code>  |

#### F.57.3.7.2. Text Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

| Function                                                                                            | Returns           |
|-----------------------------------------------------------------------------------------------------|-------------------|
| <code>pgv_set_text(package text, name text, value text, is_transactional bool default false)</code> | <code>void</code> |
| <code>pgv_get_text(package text, name text, strict bool default true)</code>                        | <code>text</code> |

#### F.57.3.7.3. Numeric Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

| Function                                                                                                  | Returns              |
|-----------------------------------------------------------------------------------------------------------|----------------------|
| <code>pgv_set_numeric(package text, name text, value numeric, is_transactional bool default false)</code> | <code>void</code>    |
| <code>pgv_get_numeric(package text, name text, strict bool default true)</code>                           | <code>numeric</code> |

#### F.57.3.7.4. Timestamp Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

| Function                                                                                                      | Returns   |
|---------------------------------------------------------------------------------------------------------------|-----------|
| <code>pgv_set_timestamp(package text, name text, value timestamp, is_transactional bool default false)</code> | void      |
| <code>pgv_get_timestamp(package text, name text, strict bool default true)</code>                             | timestamp |

#### F.57.3.7.5. Timestamp with timezone Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

| Function                                                                                                          | Returns     |
|-------------------------------------------------------------------------------------------------------------------|-------------|
| <code>pgv_set_timestamptz(package text, name text, value timestamptz, is_transactional bool default false)</code> | void        |
| <code>pgv_get_timestamptz(package text, name text, strict bool default true)</code>                               | timestamptz |

#### F.57.3.7.6. Date Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

| Function                                                                                            | Returns |
|-----------------------------------------------------------------------------------------------------|---------|
| <code>pgv_set_date(package text, name text, value date, is_transactional bool default false)</code> | void    |
| <code>pgv_get_date(package text, name text, strict bool default true)</code>                        | date    |

#### F.57.3.7.7. Jsonb Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

| Function                                                                                              | Returns |
|-------------------------------------------------------------------------------------------------------|---------|
| <code>pgv_set_jsonb(package text, name text, value jsonb, is_transactional bool default false)</code> | void    |
| <code>pgv_get_jsonb(package text, name text, strict bool default true)</code>                         | jsonb   |

### F.57.4. Important Notes

#### F.57.4.1. Collations in Collections

Collections are stored in ascending order. In the case of `text` keys, you need a collation to determine the order of elements. If no collation is specified when inserting the first element of a collection, the default collation is used. Otherwise, the specified collation is used.

#### F.57.4.2. Cursors for Set-Returning Functions

All set-returning functions except `pgv_select(package, variable)` fix their return results at first `FETCH` from the cursor and are not affected by further data manipulation.

The results of `pgv_select(package, variable)` are received dynamically and are affected by transactions/changes in the collection. For `pgv_select()` called for a transactional collection, cursors look at the snapshot of the collection when the first `FETCH` was executed, but consider changes that were made in that transaction and in committed subtransactions.

## F.57.5. Examples

Define scalar variables using the `pgv_set()` function, and then return their values using the `pgv_get()` function:

```
SELECT pgv_set('vars', 'int1', 101);
SELECT pgv_set('vars', 'int2', 102);
SELECT pgv_set('vars', 'text1', 'text variable'::text);
```

```
SELECT pgv_get('vars', 'int1', NULL::int);
pgv_get
-----
      101
```

```
SELECT pgv_get('vars', 'int2', NULL::int);
pgv_get
-----
      102
```

```
SELECT pgv_get('vars', 'text1', NULL::text);
pgv_get
-----
text variable
```

Let's assume we have the `tab` table and examine several examples of using record variables:

```
CREATE TABLE tab (id int, t varchar);
INSERT INTO tab VALUES (0, 'str00'), (1, 'str11');
```

You can use the following functions to work with record variables:

```
SELECT pgv_insert('vars', 'r1', tab) FROM tab;
```

```
SELECT pgv_select('vars', 'r1');
pgv_select
-----
(1,str11)
(0,str00)
```

```
SELECT pgv_select('vars', 'r1', 1);
pgv_select
-----
(1,str11)
```

```
SELECT pgv_select('vars', 'r1', 0);
pgv_select
-----
(0,str00)
```

```
SELECT pgv_select('vars', 'r1', ARRAY[1, 0]);
pgv_select
-----
(1,str11)
(0,str00)
```

```
SELECT pgv_delete('vars', 'r1', 1);
```

```
SELECT pgv_select('vars', 'r1');
pgv_select
-----
(0, str00)
```

Consider the behavior of a transactional variable `var_text` when changed before and after savepoints:

```
SELECT pgv_set('pack', 'var_text', 'before transaction block'::text, true);
BEGIN;
SELECT pgv_set('pack', 'var_text', 'before savepoint'::text, true);
SAVEPOINT sp1;
SELECT pgv_set('pack', 'var_text', 'savepoint sp1'::text, true);
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_text', 'savepoint sp2'::text, true);
RELEASE sp2;
SELECT pgv_get('pack', 'var_text', NULL::text);
pgv_get
-----
savepoint sp2

ROLLBACK TO sp1;
SELECT pgv_get('pack', 'var_text', NULL::text);
pgv_get
-----
before savepoint

ROLLBACK;
SELECT pgv_get('pack', 'var_text', NULL::text);
pgv_get
-----
before transaction block
```

If you create a variable after `BEGIN` or `SAVEPOINT` statements and then rollback to the previous state, the transactional variable is removed:

```
BEGIN;
SAVEPOINT sp1;
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_int', 122, true);
RELEASE SAVEPOINT sp2;
SELECT pgv_get('pack', 'var_int', NULL::int);
pgv_get
-----
122

ROLLBACK TO sp1;
SELECT pgv_get('pack', 'var_int', NULL::int);
ERROR:  unrecognized variable "var_int"
COMMIT;
```

List the available packages and variables:

```
SELECT * FROM pgv_list() ORDER BY package, name;
package | name | is_transactional
-----+-----+-----
pack    | var_text | t
vars    | int1    | f
vars    | int2    | f
```

|      |       |   |
|------|-------|---|
| vars | r1    | f |
| vars | text1 | f |

Get the amount of memory used by variables, in bytes:

```
SELECT * FROM pgv_stats() ORDER BY package;
package | allocated_memory
-----+-----
pack    |                16384
vars    |                32768
```

Delete the specified variables or packages:

```
SELECT pgv_remove('vars', 'int1');
SELECT pgv_remove('vars');
```

Delete all packages and variables:

```
SELECT pgv_free();
```

These examples show usage of collection variables and iterator functions:

```
sql
SELECT pgv_set_elem('pack', 'var', 1, 1);
SELECT pgv_set_elem('pack', 'var', 5, 5);
SELECT pgv_set_elem('pack', 'var', 10, 10);

SELECT pgv_first('pack', 'var', NULL::int);
pgv_first
-----
      1

SELECT pgv_last('pack', 'var', NULL::int);
pgv_last
-----
     10

SELECT pgv_next('pack', 'var', pgv_first('pack', 'var', NULL::int));
pgv_next
-----
      5

SELECT pgv_prior('pack', 'var', pgv_last('pack', 'var', NULL::int));
pgv_prior
-----
      5

SELECT pgv_prior('pack', 'var', pgv_first('pack', 'var', NULL::int));
pgv_prior
-----

SELECT pgv_next('pack', 'var', pgv_last('pack', 'var', NULL::int));
pgv_prior
-----

SELECT pgv_next('pack', 'var', 3);
pgv_next
-----
      5

SELECT pgv_prior('pack', 'var', 3);
pgv_prior
```

```

-----
1

SELECT pgv_get_elem('pack', 'var', pgv_last('pack', 'var', NULL::int), NULL::int);
pgv_get_elem
-----
10

SELECT pgv_remove_elem('pack', 'var', pgv_last('pack', 'var', NULL::int));
pgv_remove_elem
-----

SELECT pgv_get_elem('pack', 'var', pgv_last('pack', 'var', NULL::int), NULL::int);
pgv_get_elem
-----
5
(1 row)

```

These examples show how the collation affects the order of elements in a collection. They also show how to iterate over a whole collection with PL/pgSQL loops:

```

sql
SELECT pgv_set_elem('pack', 'var1', 'a' COLLATE "ru_RU", 'a'::text);
SELECT pgv_set_elem('pack', 'var1', 'д' COLLATE "ru_RU", 'д'::text);
SELECT pgv_set_elem('pack', 'var1', 'e' COLLATE "ru_RU", 'e'::text);
SELECT pgv_set_elem('pack', 'var1', 'ë' COLLATE "ru_RU", 'ë'::text);
SELECT pgv_set_elem('pack', 'var1', 'ж' COLLATE "ru_RU", 'ж'::text);
SELECT pgv_set_elem('pack', 'var1', 'я' COLLATE "ru_RU", 'я'::text);
DO
$$
DECLARE
    iter text;
BEGIN
    iter := pgv_first('pack', 'var1', NULL::text);
    WHILE iter IS NOT NULL LOOP
        RAISE NOTICE '%', pgv_get_elem('pack', 'var1', iter, NULL::text);
        iter := pgv_next('pack', 'var1', iter);
    END LOOP;
END;
$$;

## F.58. pg\_visibility

The `pg_visibility` module provides a means for examining the visibility map (VM) and page-level visibility information of a table. It also provides functions to check the integrity of a visibility map and to force it to be rebuilt.

Three different bits are used to store information about page-level visibility. The all-visible bit in the visibility map indicates that every tuple in the corresponding page of the relation is visible to every current and future transaction. The all-frozen bit in the visibility map indicates that every tuple in the page is frozen; that is, no future vacuum will need to modify the page until such time as a tuple is inserted, updated, deleted, or locked on that page. The page header's `PD_ALL_VISIBLE` bit has the same meaning as the all-visible bit in the visibility map, but is stored within the data page itself rather than in a separate data structure. These two bits will normally agree, but the page's all-visible bit can sometimes be set while the visibility map bit is clear after a crash recovery. The reported values can also disagree because of a change that occurs after `pg_visibility` examines the visibility map and before it examines the data page. Any event that causes data corruption can also cause these bits to disagree.

Functions that display information about `PD_ALL_VISIBLE` bits are much more costly than those that only consult the visibility map, because they must read the relation's data blocks rather than only the (much smaller) visibility map. Functions that check the relation's data blocks are similarly expensive.

### F.58.1. Functions

`pg_visibility_map(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean)` returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation.

`pg_visibility(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean)` returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation, plus the `PD_ALL_VISIBLE` bit of that block.

`pg_visibility_map(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean)` returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation.

`pg_visibility(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean)` returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation, plus the `PD_ALL_VISIBLE` bit of each block.

`pg_visibility_map_summary(relation regclass, all_visible OUT bigint, all_frozen OUT bigint)` returns record

Returns the number of all-visible pages and the number of all-frozen pages in the relation according to the visibility map.

`pg_check_frozen(relation regclass, t_ctid OUT tid)` returns setof tid

Returns the TIDs of non-frozen tuples stored in pages marked all-frozen in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_check_visible(relation regclass, t_ctid OUT tid)` returns setof tid

Returns the TIDs of non-all-visible tuples stored in pages marked all-visible in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_truncate_visibility_map(relation regclass)` returns void

Truncates the visibility map for the given relation. This function is useful if you believe that the visibility map for the relation is corrupt and wish to force rebuilding it. The first `VACUUM` executed on the given relation after this function is executed will scan every page in the relation and rebuild the visibility map. (Until that is done, queries will treat the visibility map as containing all zeroes.)

By default, these functions are executable only by superusers and members of the `pg_stat_scan_tables` role, with the exception of `pg_truncate_visibility_map(relation regclass)` which can only be executed by superusers.

## F.58.2. Author

Robert Haas <[rhaas@postgresql.org](mailto:rhaas@postgresql.org)>

## F.59. pg\_wait\_sampling

`pg_wait_sampling` is a Postgres Pro extension for collecting sampling-based statistics on wait events.

Starting from the 9.6 version, Postgres Pro Enterprise provides information about the current wait events for particular processes. However, to get descriptive statistics of the server activity, you have to sample wait events multiple times. The `pg_wait_sampling` extension automates wait events sampling by launching a special background worker. With `pg_wait_sampling` enabled, you can get the following sampling-based data:

- *Waits history* — the list of wait events for recent processes, with timestamps.
- *Waits profile* — the number of wait event samples for all processes over time (per wait event type).
- Current wait events for all processes, including background workers.

Using `pg_wait_sampling`, you can troubleshoot dependencies for queries that process longer than expected. You can see what a particular process is waiting for at each moment of time, and analyze wait events statistics. For the list of possible wait events, see [Table 27.4](#).

In combination with `pg_stat_statements`, this extension can also provide per query statistics.

### See Also

[Viewing Statistics on Wait Events](#)

[Reference](#)

### F.59.1. Installation

The `pg_wait_sampling` extension is included into Postgres Pro Enterprise and requires no special prerequisites.

To enable `pg_wait_sampling`, do the following:

1. Add `pg_wait_sampling` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'pg_wait_sampling'
```

### Important

When using the `pg_wait_sampling` with the `pg_stat_statements` extension, place `pg_stat_statements` before `pg_wait_sampling` in the `shared_preload_libraries` variable. This ensures that the `pg_stat_statements` extension does not overwrite query IDs that are used by `pg_wait_sampling`.

2. Create the `pg_wait_sampling` extension using the following query:

```
CREATE EXTENSION pg_wait_sampling;
```

3. Restart the server. Since `pg_wait_sampling` requires additional shared memory and launches a background worker, you must restart the server after adding or removing `pg_wait_sampling`.

Once the extension is created, `pg_wait_sampling` starts collecting statistics on wait events for each process. Optionally, you can change the sampling frequency and configure statistics collection modes using [GUC variables](#).

If you want to stop collecting statistics, drop the `pg_wait_sampling` extension, remove the `pg_wait_sampling` from the `shared_preload_libraries` variable, and restart the server again.

## F.59.2. Usage

### F.59.2.1. Viewing Statistics on Wait Events

When `pg_wait_sampling` is enabled, wait events are sampled each 10ms by default. You can access the collected statistics through a set of functions and views. If some of your queries appear stalled or take longer than expected, you can review all the current wait events in the `pg_wait_sampling_current` view:

```
SELECT * FROM pg_wait_sampling_current;
```

The returned statistics covers all the active processes, including background workers. To filter the view for a single process, run `pg_wait_sampling_get_current()` function specifying the process ID:

```
SELECT * FROM pg_wait_sampling_get_current(pid);
```

To better understand the dynamics of the recent wait events, you can access the `pg_wait_sampling_history` view that provides the wait events history for the latest processes:

```
SELECT * FROM pg_wait_sampling_history;
```

The returned view displays wait samples per process, with event timestamps. Waits history is implemented as an in-memory ring buffer. By default, the history size is limited to 5000 samples. To save history for a longer period of time, you can modify the `pg_wait_sampling.history_size` variable, or connect a client application to periodically read waits history and dump it to a local storage.

To monitor wait events in your database over time, use the `pg_wait_sampling_profile` view:

```
SELECT * FROM pg_wait_sampling_profile;
```

Waits profile is stored as an in-memory hash table that accumulates samples per each process and each wait event. You can reset waits profile by calling the `pg_wait_sampling_reset_profile()` function. If you connect a client to your database that periodically dumps the wait events data and resets the profile, you can save and compare statistics of wait events intensity over time.

## Important

Since wait sampling statistics is stored in RAM, make sure to reset the waits profile from time to time to avoid memory overflow.

If you are not interested in the distribution of wait events between processes, you can set the `pg_wait_sampling.profile_pid` variable to `false`. In this case, the `pid` value for each process is set to zero, and wait samples for all the processes are stored together.

## F.59.3. Reference

### F.59.3.1. GUC Variables

The `pg_wait_sampling` extension is configured with GUC variables. They are stored in the local memory and can be changed in the `postgresql.conf` file or using the `ALTER SYSTEM` command. For the changes to take effect, reload the server configuration. You can do it, for example, by calling the `pg_reload_conf()` function or executing the `pg_ctl reload` command.

`pg_wait_sampling.history_size (int4)`

Size of in-memory ring buffer for history sampling, in the number of samples.

Default: 5000

`pg_wait_sampling.history_period (int4)`

Time interval for history sampling, in milliseconds.

Default: 10

`pg_wait_sampling.profile_period (int4)`

Time interval for waits profile sampling, in milliseconds.

Default: 10

`pg_wait_sampling.profile_pid (bool)`

Sampling mode for waits profile. If set to `true`, waits profile is collected per process. If you set `pg_wait_sampling.profile_pid` to `false`, waits profile is collected for all processes together. In this case, the `pid` value for each process is set to zero, and the corresponding row contains wait samples for all the processes.

Default: `true`

`pg_wait_sampling.profile_queries (enum)`

Sampling mode for the waits profile. If `pg_wait_sampling.profile_queries` is set to `none`, the `queryid` field in views will be zero. If it is set to `top`, query IDs of only the top level statements are recorded. If it is set to `all`, query IDs of nested statements are recorded. To collect the waits profile per query, ensure that the `pg_stat_statements` extension is configured and set `pg_wait_sampling.profile_queries` to `top`. For version 14 or higher, you can compute query IDs by configuring the `compute_query_id` parameter and set the `pg_wait_sampling.profile_queries` value to `top` or `all`. For details, see [Section 19.9.2](#).

Default: `top`

`pg_wait_sampling.sample_cpu (bool)`

The sampling mode that determines whether to perform sampling of on-CPU backends. If `pg_wait_sampling.sample_cpu` is set to `true`, then sampling also includes processes that are not waiting for anything. The wait event columns for such processes will have a `NULL` value.

Default: true

## F.59.3.2. pg\_wait\_sampling Views

### F.59.3.2.1. pg\_wait\_sampling\_current View

The `pg_wait_sampling_current` view provides the information about the current wait events for all processes, including background workers.

**Table F.44. pg\_wait\_sampling\_current View**

| Column Name             | Column Type       | Description             |
|-------------------------|-------------------|-------------------------|
| <code>pid</code>        | <code>int4</code> | Process ID              |
| <code>event_type</code> | <code>text</code> | Name of wait event type |
| <code>event</code>      | <code>text</code> | Name of wait event      |
| <code>queryid</code>    | <code>int8</code> | Query ID                |

### F.59.3.2.2. pg\_wait\_sampling\_history View

The `pg_wait_sampling_history` view provides the history of wait events. This data is stored as an in-memory ring buffer.

**Table F.45. pg\_wait\_sampling\_history View**

| Column Name             | Column Type             | Description             |
|-------------------------|-------------------------|-------------------------|
| <code>pid</code>        | <code>int4</code>       | Process ID              |
| <code>ts</code>         | <code>timestampz</code> | Sample timestamp        |
| <code>event_type</code> | <code>text</code>       | Name of wait event type |
| <code>event</code>      | <code>text</code>       | Name of wait event      |
| <code>queryid</code>    | <code>int8</code>       | Query ID                |

### F.59.3.2.3. pg\_wait\_sampling\_profile View

The `pg_wait_sampling_profile` view provides the profile of wait events. This data is stored as an in-memory hash table.

**Table F.46. pg\_wait\_sampling\_profile View**

| Column Name             | Column Type       | Description             |
|-------------------------|-------------------|-------------------------|
| <code>pid</code>        | <code>int4</code> | Process ID              |
| <code>event_type</code> | <code>text</code> | Name of wait event type |
| <code>event</code>      | <code>text</code> | Name of wait event      |
| <code>queryid</code>    | <code>int8</code> | Query ID                |
| <code>count</code>      | <code>int8</code> | Number of samples       |

## F.59.3.3. Functions

`pg_wait_sampling_get_current(pid int4)`

Returns the `pg_wait_sampling_current` view with the list of current wait events. If you set the `pid` argument, the view is filtered for the process with this `pid`.

Arguments:

- `pid` — Optional. The process ID for which to display the current wait events.

`pg_wait_sampling_reset_profile()`

Resets the waits profile and clears the memory.

## F.60. plantuner

The `plantuner` module provides hints for the planner that can disable or enable indexes for query execution.

### F.60.1. Motivation

In some cases, it may be required to control the planner by providing hints that make the optimizer ignore some parts of its algorithm. There are many situations when a developer may want to temporarily disable specific index(es), without dropping them, or to instruct the planner to use a specific index.

This version of `plantuner` provides a possibility to hide the specified indexes from Postgres Pro planner, so it will not use them. For some workloads, Postgres Pro could be too pessimistic about newly created tables and assume that there are much more rows in a table than it actually has. If the `plantuner.fix_empty_table` GUC variable is set to `true`, `plantuner` sets to zero the number of pages/tuples of the table that has no blocks in a file.

### F.60.2. GUC Variables

`plantuner.disable_index` — list of indexes invisible to planner.

`plantuner.enable_index` — list of indexes visible to planner even if they are hidden by `plantuner.disable_index`.

### F.60.3. Example

To enable the module, you can either load `plantuner` shared library in a `psql` session or specify `shared_preload_libraries` option in `postgresql.conf`.

```
=# LOAD 'plantuner';
=# create table test(id int);
=# create index id_idx on test(id);
=# create index id_idx2 on test(id);
=# \d test
      Table "public.test"
  Column |  Type  | Modifiers
-----+-----+-----
   id    | integer |
Indexes:
    "id_idx" btree (id)
    "id_idx2" btree (id)
=# explain select id from test where id=1;
               QUERY PLAN
-----
Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
    -> Bitmap Index Scan on id_idx2  (cost=0.00..4.34 rows=12 width=0)
          Index Cond: (id = 1)
(4 rows)
=# set enable_seqscan=off;
=# set plantuner.disable_index='id_idx2';
=# explain select id from test where id=1;
```

```
-----
Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
    -> Bitmap Index Scan on id_idx  (cost=0.00..4.34 rows=12 width=0)
        Index Cond: (id = 1)
(4 rows)
=# set plantuner.disable_index='id_idx2,id_idx';
=# explain select id from test where id=1;
               QUERY PLAN
-----
Seq Scan on test  (cost=10000000000.00..10000000040.00 rows=12 width=4)
  Filter: (id = 1)
(2 rows)
=# set plantuner.enable_index='id_idx';
=# explain select id from test where id=1;
               QUERY PLAN
-----
Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
    -> Bitmap Index Scan on id_idx  (cost=0.00..4.34 rows=12 width=0)
        Index Cond: (id = 1)
(4 rows)
```

## F.60.4. Authors

## F.61. postgres\_fdw

The `postgres_fdw` module provides the foreign-data wrapper `postgres_fdw`, which can be used to access data stored in external Postgres Pro servers.

The functionality provided by this module overlaps substantially with the functionality of the older `dblink` module. But `postgres_fdw` provides more transparent and standards-compliant syntax for accessing remote tables, and can give better performance in many cases.

To prepare for remote access using `postgres_fdw`:

1. Install the `postgres_fdw` extension using [CREATE EXTENSION](#).
2. Create a foreign server object, using [CREATE SERVER](#), to represent each remote database you want to connect to. Specify connection information, except `user` and `password`, as options of the server object.
3. Create a user mapping, using [CREATE USER MAPPING](#), for each database user you want to allow to access each foreign server. Specify the remote user name and password to use as `user` and `password` options of the user mapping.
4. Create a foreign table, using [CREATE FOREIGN TABLE](#) or [IMPORT FOREIGN SCHEMA](#), for each remote table you want to access. The columns of the foreign table must match the referenced remote table. You can, however, use table and/or column names different from the remote table's, if you specify the correct remote names as options of the foreign table object.

Now you need only `SELECT` from a foreign table to access the data stored in its underlying remote table. You can also modify the remote table using `INSERT`, `UPDATE`, `DELETE`, `COPY`, or `TRUNCATE`. (Of course, the remote user you have specified in your user mapping must have privileges to do these things.)

Note that the `ONLY` option specified in `SELECT`, `UPDATE`, `DELETE` or `TRUNCATE` has no effect when accessing or modifying the remote table.

Note that `postgres_fdw` currently lacks support for `INSERT` statements with an `ON CONFLICT DO UPDATE` clause. However, the `ON CONFLICT DO NOTHING` clause is supported, provided a unique index inference specification is omitted. Note also that `postgres_fdw` supports row movement invoked by `UPDATE` statements executed on partitioned tables, but it currently does not handle the case where a remote partition chosen to insert a moved row into is also an `UPDATE` target partition that will be updated elsewhere in the same command.

It is generally recommended that the columns of a foreign table be declared with exactly the same data types, and collations if applicable, as the referenced columns of the remote table. Although `postgres_fdw` is currently rather forgiving about performing data type conversions at need, surprising semantic anomalies may arise when types or collations do not match, due to the remote server interpreting query conditions differently from the local server.

Note that a foreign table can be declared with fewer columns, or with a different column order, than its underlying remote table has. Matching of columns to the remote table is by name, not position.

## F.61.1. FDW Options of `postgres_fdw`

### F.61.1.1. Connection Options

A foreign server using the `postgres_fdw` foreign data wrapper can have the same options that `libpq` accepts in connection strings, as described in [Section 36.1.2](#), except that these options are not allowed or have special handling:

- `user`, `password` and `sslpassword` (specify these in a user mapping, instead, or use a service file)
- `client_encoding` (this is automatically set from the local server encoding)
- `fallback_application_name` (always set to `postgres_fdw`)
- `sslkey` and `sslcert` - these may appear in *either or both* a connection and a user mapping. If both are present, the user mapping setting overrides the connection setting.

Only superusers may create or modify user mappings with the `sslcert` or `sslkey` settings.

Only superusers may connect to foreign servers without password authentication, so always specify the `password` option for user mappings belonging to non-superusers.

A superuser may override this check on a per-user-mapping basis by setting the user mapping option `password_required` `'false'`, e.g.,

```
ALTER USER MAPPING FOR some_non_superuser SERVER loopback_nopw
OPTIONS (ADD password_required 'false');
```

To prevent unprivileged users from exploiting the authentication rights of the unix user the postgres server is running as to escalate to superuser rights, only the superuser may set this option on a user mapping.

Care is required to ensure that this does not allow the mapped user the ability to connect as superuser to the mapped database per CVE-2007-3278 and CVE-2007-6601. Don't set `password_required=false` on the `public` role. Keep in mind that the mapped user can potentially use any client certificates, `.pgpass`, `.pg_service.conf` etc in the unix home directory of the system user the postgres server runs as. They can also use any trust relationship granted by authentication modes like `peer` or `ident` authentication.

### F.61.1.2. Object Name Options

These options can be used to control the names used in SQL statements sent to the remote Postgres Pro server. These options are needed when a foreign table is created with names different from the underlying remote table's names.

`schema_name`

This option, which can be specified for a foreign table, gives the schema name to use for the foreign table on the remote server. If this option is omitted, the name of the foreign table's schema is used.

`table_name`

This option, which can be specified for a foreign table, gives the table name to use for the foreign table on the remote server. If this option is omitted, the foreign table's name is used.

`column_name`

This option, which can be specified for a column of a foreign table, gives the column name to use for the column on the remote server. If this option is omitted, the column's name is used.

### F.61.1.3. Cost Estimation Options

`postgres_fdw` retrieves remote data by executing queries against remote servers, so ideally the estimated cost of scanning a foreign table should be whatever it costs to be done on the remote server, plus some overhead for communication. The most reliable way to get such an estimate is to ask the remote server and then add something for overhead — but for simple queries, it may not be worth the cost of an additional remote query to get a cost estimate. So `postgres_fdw` provides the following options to control how cost estimation is done:

`use_remote_estimate`

This option, which can be specified for a foreign table or a foreign server, controls whether `postgres_fdw` issues remote `EXPLAIN` commands to obtain cost estimates. A setting for a foreign table overrides any setting for its server, but only for that table. The default is `false`.

`fdw_startup_cost`

This option, which can be specified for a foreign server, is a floating point value that is added to the estimated startup cost of any foreign-table scan on that server. This represents the additional overhead of establishing a connection, parsing and planning the query on the remote side, etc. The default value is 100.

`fdw_tuple_cost`

This option, which can be specified for a foreign server, is a floating point value that is used as extra cost per-tuple for foreign-table scans on that server. This represents the additional overhead of data transfer between servers. You might increase or decrease this number to reflect higher or lower network delay to the remote server. The default value is 0.01.

When `use_remote_estimate` is `true`, `postgres_fdw` obtains row count and cost estimates from the remote server and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. When `use_remote_estimate` is `false`, `postgres_fdw` performs local row count and cost estimation and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. This local estimation is unlikely to be very accurate unless local copies of the remote table's statistics are available. Running [ANALYZE](#) on the foreign table is the way to update the local statistics; this will perform a scan of the remote table and then calculate and store statistics just as though the table were local. Keeping local statistics can be a useful way to reduce per-query planning overhead for a remote table — but if the remote table is frequently updated, the local statistics will soon be obsolete.

### F.61.1.4. Remote Execution Options

By default, only `WHERE` clauses using built-in operators and functions will be considered for execution on the remote server. Clauses involving non-built-in functions are checked locally after rows are fetched. If such functions are available on the remote server and can be relied on to produce the same results as they do locally, performance can be improved by sending such `WHERE` clauses for remote execution. This behavior can be controlled using the following option:

`extensions`

This option is a comma-separated list of names of Postgres Pro extensions that are installed, in compatible versions, on both the local and remote servers. Functions and operators that are immutable and belong to a listed extension will be considered shippable to the remote server. This option can only be specified for foreign servers, not per-table.

When using the `extensions` option, *it is the user's responsibility* that the listed extensions exist and behave identically on both the local and remote servers. Otherwise, remote queries may fail or behave unexpectedly.

`fetch_size`

This option specifies the number of rows `postgres_fdw` should get in each fetch operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 100.

`batch_size`

This option specifies the number of rows `postgres_fdw` should insert in each insert operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 1.

Note the actual number of rows `postgres_fdw` inserts at once depends on the number of columns and the provided `batch_size` value. The batch is executed as a single query, and the libpq protocol (which `postgres_fdw` uses to connect to a remote server) limits the number of parameters in a single query to 65535. When the number of columns \* `batch_size` exceeds the limit, the `batch_size` will be adjusted to avoid an error.

### F.61.1.5. Asynchronous Execution Options

`postgres_fdw` supports asynchronous execution, which runs multiple parts of an `Append` node concurrently rather than serially to improve performance. This execution can be controlled using the following option:

`async_capable`

This option controls whether `postgres_fdw` allows foreign tables to be scanned concurrently for asynchronous execution. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `false`.

In order to ensure that the data being returned from a foreign server is consistent, `postgres_fdw` will only open one connection for a given foreign server and will run all queries against that server sequentially even if there are multiple foreign tables involved, unless those tables are subject to different user mappings. In such a case, it may be more performant to disable this option to eliminate the overhead associated with running queries asynchronously.

Asynchronous execution is applied even when an `Append` node contains subplan(s) executed synchronously as well as subplan(s) executed asynchronously. In such a case, if the asynchronous subplans are ones processed using `postgres_fdw`, tuples from the asynchronous subplans are not returned until after at least one synchronous subplan returns all tuples, as that subplan is executed while the asynchronous subplans are waiting for the results of asynchronous queries sent to foreign servers. This behavior might change in a future release.

### F.61.1.6. Updatability Options

By default all foreign tables using `postgres_fdw` are assumed to be updatable. This may be overridden using the following option:

`updatable`

This option controls whether `postgres_fdw` allows foreign tables to be modified using `INSERT`, `UPDATE` and `DELETE` commands. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact updatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server. Note however that the `information_schema` views will report a `postgres_fdw` foreign table to be updatable (or not) according to the setting of this option, without any check of the remote server.

### F.61.1.7. Truncatability Options

By default all foreign tables using `postgres_fdw` are assumed to be truncatable. This may be overridden using the following option:

`truncatable`

This option controls whether `postgres_fdw` allows foreign tables to be truncated using the `TRUNCATE` command. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact truncatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server.

### F.61.1.8. Importing Options

`postgres_fdw` is able to import foreign table definitions using [IMPORT FOREIGN SCHEMA](#). This command creates foreign table definitions on the local server that match tables or views present on the remote server. If the remote tables to be imported have columns of user-defined data types, the local server must have compatible types of the same names.

Importing behavior can be customized with the following options (given in the `IMPORT FOREIGN SCHEMA` command):

`import_collate`

This option controls whether column `COLLATE` options are included in the definitions of foreign tables imported from a foreign server. The default is `true`. You might need to turn this off if the remote server has a different set of collation names than the local server does, which is likely to be the case if it's running on a different operating system. If you do so, however, there is a very severe risk that the imported table columns' collations will not match the underlying data, resulting in anomalous query behavior.

Even when this parameter is set to `true`, importing columns whose collation is the remote server's default can be risky. They will be imported with `COLLATE "default"`, which will select the local server's default collation, which could be different.

`import_default`

This option controls whether column `DEFAULT` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `false`. If you enable this option, be wary of defaults that might get computed differently on the local server than they would be on the remote server; `nextval()` is a common source of problems. The `IMPORT` will fail altogether if an imported default expression uses a function or operator that does not exist locally.

`import_generated`

This option controls whether column `GENERATED` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `true`. The `IMPORT` will fail altogether if an imported generated expression uses a function or operator that does not exist locally.

`import_not_null`

This option controls whether column `NOT NULL` constraints are included in the definitions of foreign tables imported from a foreign server. The default is `true`.

Note that constraints other than `NOT NULL` will never be imported from the remote tables. Although Postgres Pro does support check constraints on foreign tables, there is no provision for importing them automatically, because of the risk that a constraint expression could evaluate differently on the local and remote servers. Any such inconsistency in the behavior of a check constraint could lead to hard-to-detect errors in query optimization. So if you wish to import check constraints, you must do so manually,

and you should verify the semantics of each one carefully. For more detail about the treatment of check constraints on foreign tables, see [CREATE FOREIGN TABLE](#).

Tables or foreign tables which are partitions of some other table are imported only when they are explicitly specified in `LIMIT TO` clause. Otherwise they are automatically excluded from [IMPORT FOREIGN SCHEMA](#). Since all data can be accessed through the partitioned table which is the root of the partitioning hierarchy, importing only partitioned tables should allow access to all the data without creating extra objects.

### F.61.1.9. Connection Management Options

By default, all connections that `postgres_fdw` establishes to foreign servers are kept open in the local session for re-use.

`keep_connections`

This option controls whether `postgres_fdw` keeps the connections to the foreign server open so that subsequent queries can re-use them. It can only be specified for a foreign server. The default is `on`. If set to `off`, all connections to this foreign server will be discarded at the end of each transaction.

### F.61.2. Functions

`postgres_fdw_get_connections(OUT server_name text, OUT valid boolean)` returns `setof record`

This function returns the foreign server names of all the open connections that `postgres_fdw` established from the local session to the foreign servers. It also returns whether each connection is valid or not. `false` is returned if the foreign server connection is used in the current local transaction but its foreign server or user mapping is changed or dropped (Note that server name of an invalid connection will be `NULL` if the server is dropped), and then such invalid connection will be closed at the end of that transaction. `true` is returned otherwise. If there are no open connections, no record is returned. Example usage of the function:

```
postgres=# SELECT * FROM postgres_fdw_get_connections() ORDER BY 1;
 server_name | valid 
-----+-----
 loopback1  | t
 loopback2  | f
```

`postgres_fdw_disconnect(server_name text)` returns `boolean`

This function discards the open connections that are established by `postgres_fdw` from the local session to the foreign server with the given name. Note that there can be multiple connections to the given server using different user mappings. If the connections are used in the current local transaction, they are not disconnected and warning messages are reported. This function returns `true` if it disconnects at least one connection, otherwise `false`. If no foreign server with the given name is found, an error is reported. Example usage of the function:

```
postgres=# SELECT postgres_fdw_disconnect('loopback1');
 postgres_fdw_disconnect 
-----
 t
```

`postgres_fdw_disconnect_all()` returns `boolean`

This function discards all the open connections that are established by `postgres_fdw` from the local session to foreign servers. If the connections are used in the current local transaction, they are not disconnected and warning messages are reported. This function returns `true` if it disconnects at least one connection, otherwise `false`. Example usage of the function:

```
postgres=# SELECT postgres_fdw_disconnect_all();
 postgres_fdw_disconnect_all 
-----
```

## F.61.3. Connection Management

`postgres_fdw` establishes a connection to a foreign server during the first query that uses a foreign table associated with the foreign server. By default this connection is kept and re-used for subsequent queries in the same session. This behavior can be controlled using `keep_connections` option for a foreign server. If multiple user identities (user mappings) are used to access the foreign server, a connection is established for each user mapping.

When changing the definition of or removing a foreign server or a user mapping, the associated connections are closed. But note that if any connections are in use in the current local transaction, they are kept until the end of the transaction. Closed connections will be re-established when they are necessary by future queries using a foreign table.

Once a connection to a foreign server has been established, it's by default kept until the local or corresponding remote session exits. To disconnect a connection explicitly, `keep_connections` option for a foreign server may be disabled, or `postgres_fdw_disconnect` and `postgres_fdw_disconnect_all` functions may be used. For example, these are useful to close connections that are no longer necessary, thereby releasing connections on the foreign server.

## F.61.4. Transaction Management

During a query that references any remote tables on a foreign server, `postgres_fdw` opens a transaction on the remote server if one is not already open corresponding to the current local transaction. The remote transaction is committed or aborted when the local transaction commits or aborts. Savepoints are similarly managed by creating corresponding remote savepoints.

The remote transaction uses `SERIALIZABLE` isolation level when the local transaction has `SERIALIZABLE` isolation level; otherwise it uses `REPEATABLE READ` isolation level. This choice ensures that if a query performs multiple table scans on the remote server, it will get snapshot-consistent results for all the scans. A consequence is that successive queries within a single transaction will see the same data from the remote server, even if concurrent updates are occurring on the remote server due to other activities. That behavior would be expected anyway if the local transaction uses `SERIALIZABLE` or `REPEATABLE READ` isolation level, but it might be surprising for a `READ COMMITTED` local transaction. A future Postgres Pro release might modify these rules.

Note that it is currently not supported by `postgres_fdw` to prepare the remote transaction for two-phase commit.

## F.61.5. Remote Query Optimization

`postgres_fdw` attempts to optimize remote queries to reduce the amount of data transferred from foreign servers. This is done by sending query `WHERE` clauses to the remote server for execution, and by not retrieving table columns that are not needed for the current query. To reduce the risk of misexecution of queries, `WHERE` clauses are not sent to the remote server unless they use only data types, operators, and functions that are built-in or belong to an extension that's listed in the foreign server's `extensions` option. Operators and functions in such clauses must be `IMMUTABLE` as well. For an `UPDATE` or `DELETE` query, `postgres_fdw` attempts to optimize the query execution by sending the whole query to the remote server if there are no query `WHERE` clauses that cannot be sent to the remote server, no local joins for the query, no row-level local `BEFORE` or `AFTER` triggers or stored generated columns on the target table, and no `CHECK OPTION` constraints from parent views. In `UPDATE`, expressions to assign to target columns must use only built-in data types, `IMMUTABLE` operators, or `IMMUTABLE` functions, to reduce the risk of misexecution of the query.

When `postgres_fdw` encounters a join between foreign tables on the same foreign server, it sends the entire join to the foreign server, unless for some reason it believes that it will be more efficient to fetch rows from each table individually, or unless the table references involved are subject to different user mappings. While sending the `JOIN` clauses, it takes the same precautions as mentioned above for the `WHERE` clauses.

The query that is actually sent to the remote server for execution can be examined using `EXPLAIN VERBOSE`.

## F.61.6. Remote Query Execution Environment

In the remote sessions opened by `postgres_fdw`, the `search_path` parameter is set to just `pg_catalog`, so that only built-in objects are visible without schema qualification. This is not an issue for queries generated by `postgres_fdw` itself, because it always supplies such qualification. However, this can pose a hazard for functions that are executed on the remote server via triggers or rules on remote tables. For example, if a remote table is actually a view, any functions used in that view will be executed with the restricted search path. It is recommended to schema-qualify all names in such functions, or else attach `SET search_path` options (see [CREATE FUNCTION](#)) to such functions to establish their expected search path environment.

`postgres_fdw` likewise establishes remote session settings for various parameters:

- `TimeZone` is set to UTC
- `DateStyle` is set to ISO
- `IntervalStyle` is set to postgres
- `extra_float_digits` is set to 3 for remote servers 9.0 and newer and is set to 2 for older versions

These are less likely to be problematic than `search_path`, but can be handled with function `SET` options if the need arises.

It is *not* recommended that you override this behavior by changing the session-level settings of these parameters; that is likely to cause `postgres_fdw` to malfunction.

## F.61.7. Cross-Version Compatibility

`postgres_fdw` can be used with remote servers dating back to PostgreSQL 8.3. Read-only capability is available back to 8.1. A limitation however is that `postgres_fdw` generally assumes that immutable built-in functions and operators are safe to send to the remote server for execution, if they appear in a `WHERE` clause for a foreign table. Thus, a built-in function that was added since the remote server's release might be sent to it for execution, resulting in “function does not exist” or a similar error. This type of failure can be worked around by rewriting the query, for example by embedding the foreign table reference in a sub-`SELECT` with `OFFSET 0` as an optimization fence, and placing the problematic function or operator outside the sub-`SELECT`.

## F.61.8. Configuration Parameters

`postgres_fdw.read_only_transactions` (boolean)

Enables read-only queries to foreign tables in read-write transactions. If set to `on`, all remote transactions executed by the extension are created as `READ ONLY`.

## F.61.9. Examples

Here is an example of creating a foreign table with `postgres_fdw`. First install the extension:

```
CREATE EXTENSION postgres_fdw;
```

Then create a foreign server using [CREATE SERVER](#). In this example we wish to connect to a Postgres Pro server on host `192.83.123.89` listening on port `5432`. The database to which the connection is made is named `foreign_db` on the remote server:

```
CREATE SERVER foreign_server
    FOREIGN DATA WRAPPER postgres_fdw
    OPTIONS (host '192.83.123.89', port '5432', dbname 'foreign_db');
```

A user mapping, defined with [CREATE USER MAPPING](#), is needed as well to identify the role that will be used on the remote server:

```
CREATE USER MAPPING FOR local_user
    SERVER foreign_server
```

```
OPTIONS (user 'foreign_user', password 'password');
```

Now it is possible to create a foreign table with [CREATE FOREIGN TABLE](#). In this example we wish to access the table named `some_schema.some_table` on the remote server. The local name for it will be `foreign_table`:

```
CREATE FOREIGN TABLE foreign_table (  
    id integer NOT NULL,  
    data text  
)  
  
    SERVER foreign_server  
    OPTIONS (schema_name 'some_schema', table_name 'some_table');
```

It's essential that the data types and other properties of the columns declared in `CREATE FOREIGN TABLE` match the actual remote table. Column names must match as well, unless you attach `column_name` options to the individual columns to show how they are named in the remote table. In many cases, use of [IMPORT FOREIGN SCHEMA](#) is preferable to constructing foreign table definitions manually.

Shigeru Hanada <shigeru.hanada@gmail.com>

## F.62. ptrack

PTRACK is a block-level incremental backup engine for Postgres Pro. If PTRACK is enabled, backup tools like [pg\\_probackup](#) can use its API to get information on the changed blocks on the fly when taking incremental backups. Copying only those blocks that have changed since the previous backup can significantly speed up the creation and minimize the size of backups.

PTRACK is designed to allow false positives, but to never allow false negatives: it means that all changes within the data directory except hint bits are guaranteed to be marked in the PTRACK map file, although some unchanged blocks might be included as well.

### F.62.1. Setting up PTRACK

Once you complete Postgres Pro Enterprise installation, do the following:

1. Add `ptrack` to the [shared\\_preload\\_libraries](#) parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'ptrack'
```

2. Set [ptrack.map\\_size](#) parameter to a positive integer.

For optimal performance, it is recommended to set `ptrack.map_size` to  $N / 1024$ , where  $N$  is the size of the Postgres Pro cluster, in MB. If you set this parameter to a lower value, PTRACK is more likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the incremental backup.

Setting `ptrack.map_size` to a higher value does not affect PTRACK operation, but keep in mind that you need up to `ptrack.map_size * 3` MB of additional disk space since PTRACK uses two additional temporary files to ensure durability. It is not recommended to set this parameter to a value higher than 1024. Even for Postgres Pro clusters with  $N > 1$  TB, it makes sense to use a higher value only if the efficiency and sizes of backups are more critical than the potential overhead of maintaining a large PTRACK map.

3. Check the [wal\\_level](#) setting. When using PTRACK, it is required to set the [wal\\_level](#) parameter to `replica` or higher. Otherwise, you can lose some tracked changes if crash-recovery occurs: some commands do not write WAL at all if `wal_level` is `minimal`, and PTRACK map files are flushed to disk only at checkpoint time.
4. Restart the Postgres Pro Enterprise instance for the changes to take effect, and then create the PTRACK extension:

```
CREATE EXTENSION ptrack;
```

As a result, several PTRACK functions are created, which are required for accessing PTRACK data. Once this setup is complete, PTRACK starts tracking all the page changes in the Postgres Pro cluster and creates a `ptrack.map` file that stores the latest LSN values for these pages.

### Note

The `ptrack.map_size` parameter can only be set at server start. If you change this parameter, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. To avoid losing recent changes, it is recommended to retake a full backup after modifying this setting.

## F.62.2. PTRACK Configuration Parameters

`ptrack.map_size` (integer)

Specifies the size of a PTRACK map file and the amount of shared memory allocated for this file, in MB. The PTRACK map file stores the latest LSN values for all pages of the Postgres Pro cluster that have changed since PTRACK was enabled. It is not recommended to set this parameter to a value higher than 1GB. The 0 value disables PTRACK and cleans up all the related service files.

The `ptrack.map_size` parameter can only be set at server start. If you change this parameter, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. To avoid losing recent changes, it is recommended to retake a full backup after modifying this setting.

Default: 0

## F.62.3. PTRACK Functions

`ptrack_init_lsn()` returns `pg_lsn`

Returns the LSN of the last PTRACK map initialization.

`ptrack_get_pagemapset(start_lsn pg_lsn)` returns `setof record`

Returns a list of data files changed since the specified `start_lsn` with the number and bitmap of changed pages for each file.

For example:

```
postgres=# SELECT * FROM ptrack_get_pagemapset('0/185C8C0');
```

| path | pagecount | pagemap |
|------|-----------|---------|
|------|-----------|---------|

|                 |   |                                    |
|-----------------|---|------------------------------------|
| base/16384/1255 | 3 | \x001000000005000000000000         |
| base/16384/2674 | 3 | \x0000000900010000000000000000     |
| base/16384/2691 | 1 | \x00004000000000000000000000       |
| base/16384/2608 | 1 | \x00000000000000040000000000000000 |
| base/16384/2690 | 1 | \x00040000000000000000000000       |

`ptrack_get_change_stat(start_lsn pg_lsn)` returns `record`

Returns the statistics of changes (number of files, number of changed pages and their total size in MB) since the specified `start_lsn`.

For example:

```
postgres=# SELECT * FROM ptrack_get_change_stat('0/285C8C8');
```

| files | pages | size, MB |
|-------|-------|----------|
|-------|-------|----------|

`ptrack_version()` returns text

Returns PTRACK version.

## F.63. referee

`referee` is a Postgres Pro Enterprise extension for managing quorum settings in clusters with an even number of nodes configured with [multimaster](#). Installed on a separate system, the `referee` extension provides a voting node to assign the quorum status to a subset of nodes if only half of the cluster nodes remain connected to each other.

If a multi-master cluster is split into equal parts, or half of the cluster nodes fail, each subset of nodes that equals half of the cluster tries to access the referee. The first subset that gets connected to the referee wins the voting and continues working, while all the other nodes are excluded from the cluster to avoid split-brain problems.

The referee node does not store any cluster data, so it is very lightweight and can be located on systems with limited resources. For details on how to set up and use a referee node with `multimaster`, see [Section F.33.3.3](#).

### F.63.1. Authors

Postgres Professional, Moscow, Russia

## F.64. rum

### F.64.1. Introduction

The **rum** module provides access method to work with the `RUM` indexes. It is based on the `GIN` access method code.

`GIN` index allows you to perform fast full-text search using `tsvector` and `tsquery` types. However, full-text search with `GIN` index has some performance issues because positional and other additional information is not stored.

`RUM` solves these issues by storing additional information in a posting tree. As compared to `GIN`, `RUM` index has the following benefits:

- Faster ranking. Ranking requires positional information. And after the index scan we do not need an additional heap scan to retrieve lexeme positions because `RUM` index stores them.
- Faster phrase search. This improvement is related to the previous one as phrase search also needs positional information.
- Faster ordering by timestamp. `RUM` index stores additional information together with lexemes, so it is not necessary to perform a heap scan.
- A possibility to perform depth-first search and therefore return first results immediately.

The drawback of `RUM` is that it has slower build and insert time as compared to `GIN` because `RUM` stores additional information together with keys and uses generic WAL records.

### F.64.2. Installation

`rum` is a Postgres Pro Enterprise extension and it has no special prerequisites.

Install extension as follows:

```
$ psql dbname -c "CREATE EXTENSION rum"
```

### F.64.3. Common Operators

The operators provided by the `rum` module are shown in [Table F.47](#):

**Table F.47. rum Operators**

| Operator                                   | Returns             | Description                                                                     |
|--------------------------------------------|---------------------|---------------------------------------------------------------------------------|
| <code>tsvector &lt;=&gt; tsquery</code>    | <code>float4</code> | Returns distance between <code>tsvector</code> and <code>tsquery</code> values. |
| <code>timestamp &lt;=&gt; timestamp</code> | <code>float8</code> | Returns distance between two <code>timestamp</code> values.                     |
| <code>timestamp &lt;=  timestamp</code>    | <code>float8</code> | Returns distance only for ascending <code>timestamp</code> values.              |
| <code>timestamp  =&gt; timestamp</code>    | <code>float8</code> | Returns distance only for descending <code>timestamp</code> values.             |

### Note

`rum` introduces its own ranking function that is executed inside the `<=>` operator. It calculates the score (inverted distance) using the specified normalization method. This function is a combination of `ts_rank` and `ts_rank_cd` (see [Section 9.13](#) for details). While `ts_rank` does not support logical operators and `ts_rank_cd` works poorly with OR queries, the `rum`-specific ranking function overcomes these drawbacks.

## F.64.4. Operator Classes

The `rum` extension provides the following operator classes:

`rum_tsvector_ops`

Stores `tsvector` lexemes with positional information. Supports ordering by `<=>` operator and prefix search.

`rum_tsvector_hash_ops`

Stores hash of `tsvector` lexemes with positional information. Supports ordering by `<=>` operator, but does not support prefix search.

`rum_tsvector_addon_ops`

Stores `tsvector` lexemes with additional data of any type supported by `RUM`.

### Note

To use the `rum_tsvector_addon_ops` operator class, when creating the `RUM` index with `CREATE INDEX`, specify the `attach` and `to` storage parameters in the `WITH` clause.

`rum_tsvector_hash_addon_ops`

Stores `tsvector` lexemes with additional data of any type supported by `RUM`. Does not support prefix search.

`rum_tsquery_ops`

Stores branches of query tree in additional information.

`rum_anyarray_ops`

Stores `anyarray` elements with length of the array. Supports ordering by `<=>` operator.

Indexable operators: `&&` `@>` `<@` `=` `%`

`rum_anyarray_addon_ops`

Stores `anyarray` elements with additional data of any type supported by `RUM`.

`rum_type_ops`

Stores lexemes of the corresponding type with positional information. The *type* placeholder in the class name must be substituted by one of the following type names: `int2`, `int4`, `int8`, `float4`, `float8`, `money`, `oid`, `timestamp`, `timestampz`, `time`, `timetz`, `date`, `interval`, `macaddr`, `inet`, `cidr`, `text`, `varchar`, `char`, `bytea`, `bit`, `varbit`, `numeric`.

`rum_type_ops` supports ordering by `<=>`, `<=|`, and `|=>` operators. This operator class can be used together with `rum_tsvector_addon_ops`, `rum_tsvector_hash_addon_ops`, and `rum_anyarray_addon_ops` operator classes.

Supported indexable operators depend on the data type:

- `<` `<=` `=` `>=` `>` `<=>` `<=|` `|=>` are supported for `int2`, `int4`, `int8`, `float4`, `float8`, `money`, `oid`, `timestamp`, `timestampz`.
- `<` `<=` `=` `>=` `>` are supported for `time`, `timetz`, `date`, `interval`, `macaddr`, `inet`, `cidr`, `text`, `varchar`, `char`, `bytea`, `bit`, `varbit`, `numeric`.

### Note

The following operator classes are now deprecated: `rum_tsvector_timestamp_ops`, `rum_tsvector_timestampz_ops`, `rum_tsvector_hash_timestamp_ops`, `rum_tsvector_hash_timestampz_ops`.

## F.64.5. Examples

### F.64.5.1. `rum_tsvector_ops` Example

Let's assume we have the following table:

```
CREATE TABLE test_rum(t text, a tsvector);

CREATE TRIGGER tsvectorupdate
BEFORE UPDATE OR INSERT ON test_rum
FOR EACH ROW EXECUTE PROCEDURE tsvector_update_trigger('a', 'pg_catalog.english', 't');

INSERT INTO test_rum(t) VALUES ('The situation is most beautiful');
INSERT INTO test_rum(t) VALUES ('It is a beautiful');
INSERT INTO test_rum(t) VALUES ('It looks like a beautiful place');
```

Then we can create a new index:

```
CREATE INDEX rumidx ON test_rum USING rum (a rum_tsvector_ops);
```

And we can execute the following queries:

```
SELECT t, a <=> to_tsquery('english', 'beautiful | place') AS rank
FROM test_rum
WHERE a @@ to_tsquery('english', 'beautiful | place')
ORDER BY a <=> to_tsquery('english', 'beautiful | place');
      t              | rank
-----+-----
The situation is most beautiful | 0.0303964
It is a beautiful              | 0.0303964
It looks like a beautiful place | 0.0607927
(3 rows)
```

```
SELECT t, a <=> to_tsquery('english', 'place | situation') AS rank
FROM test_rum
```

```
WHERE a @@ to_tsquery('english', 'place | situation')
ORDER BY a <=> to_tsquery('english', 'place | situation');
      t              |      rank
```

```
-----+-----
The situation is most beautiful | 0.0303964
It looks like a beautiful place | 0.0303964
(2 rows)
```

### F.64.5.2. rum\_tsvector\_addon\_ops Example

Let's assume we have the following table:

```
CREATE TABLE tsts (id int, t tsvector, d timestamp);

\copy tsts from 'rum/data/tsts.data'

CREATE INDEX tsts_idx ON tsts USING rum (t rum_tsvector_addon_ops, d)
WITH (attach = 'd', to = 't');
```

Now we can execute the following queries:

```
EXPLAIN (costs off)
  SELECT id, d, d <=> '2016-05-16 14:21:25' FROM tsts WHERE t @@ 'wr&qh' ORDER BY d
 <=> '2016-05-16 14:21:25' LIMIT 5;
                                QUERY PLAN
```

```
-----+-----
Limit
->  Index Scan using tsts_idx on tsts
      Index Cond: (t @@ '''wr'' & ''qh''::tsquery)
      Order By: (d <=> 'Mon May 16 14:21:25 2016'::timestamp without time zone)
(4 rows)
```

```
SELECT id, d, d <=> '2016-05-16 14:21:25' FROM tsts WHERE t @@ 'wr&qh' ORDER BY d <=>
 '2016-05-16 14:21:25' LIMIT 5;
 id |              d              |      ?column?
-----+-----+-----
355 | Mon May 16 14:21:22.326724 2016 |      2.673276
354 | Mon May 16 13:21:22.326724 2016 |     3602.673276
371 | Tue May 17 06:21:22.326724 2016 |     57597.326724
406 | Wed May 18 17:21:22.326724 2016 |    183597.326724
415 | Thu May 19 02:21:22.326724 2016 |   215997.326724
(5 rows)
```

### F.64.5.3. rum\_tsquery\_ops Example

Suppose we have the table:

```
CREATE TABLE query (q tsquery, tag text);

INSERT INTO query VALUES ('supernova & star', 'sn'),
 ('black', 'color'),
 ('big & bang & black & hole', 'bang'),
 ('spiral & galaxy', 'shape'),
 ('black & hole', 'color');

CREATE INDEX query_idx ON query USING rum(q);
```

We can execute the following fast query:

```
SELECT * FROM query
  WHERE to_tsvector('black holes never exists before we think about them') @@ q;
      q              |      tag
```

```
-----+-----
'black'          | color
'black' & 'hole' | color
(2 rows)
```

#### F.64.5.4. rum\_anyarray\_ops Example

Let's assume we have the following table:

```
CREATE TABLE test_array (i int2[]);

INSERT INTO test_array VALUES ('{}'), ('{0}'), ('{1,2,3,4}'), ('{1,2,3}'), ('{1,2}'),
    ('{1}');

CREATE INDEX idx_array ON test_array USING rum (i rum_anyarray_ops);
```

Now we can execute the following query using index scan:

```
SET enable_seqscan TO off;

EXPLAIN (COSTS OFF) SELECT * FROM test_array WHERE i && '{1}' ORDER BY i <=> '{1}' ASC;
      QUERY PLAN
-----
Index Scan using idx_array on test_array
  Index Cond: (i && '{1}'::smallint[])
  Order By: (i <=> '{1}'::smallint[])
(3 rows)

SELECT * FROM test_array WHERE i && '{1}' ORDER BY i <=> '{1}' ASC;
      i
-----
 {1}
 {1,2}
 {1,2,3}
 {1,2,3,4}
(4 rows)
```

#### F.64.6. Authors

Alexander Korotkov

Oleg Bartunov

Teodor Sigaev

### F.65. seg

This module implements a data type `seg` for representing line segments, or floating point intervals. `seg` can represent uncertainty in the interval endpoints, making it especially useful for representing laboratory measurements.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

#### F.65.1. Rationale

The geometry of measurements is usually more complex than that of a point in a numeric continuum. A measurement is usually a segment of that continuum with somewhat fuzzy limits. The measurements come out as intervals because of uncertainty and randomness, as well as because the value being measured may naturally be an interval indicating some condition, such as the temperature range of stability of a protein.

Using just common sense, it appears more convenient to store such data as intervals, rather than pairs of numbers. In practice, it even turns out more efficient in most applications.

Further along the line of common sense, the fuzziness of the limits suggests that the use of traditional numeric data types leads to a certain loss of information. Consider this: your instrument reads 6.50, and you input this reading into the database. What do you get when you fetch it? Watch:

```
test=> select 6.50 :: float8 as "pH";
pH
---
6.5
(1 row)
```

In the world of measurements, 6.50 is not the same as 6.5. It may sometimes be critically different. The experimenters usually write down (and publish) the digits they trust. 6.50 is actually a fuzzy interval contained within a bigger and even fuzzier interval, 6.5, with their center points being (probably) the only common feature they share. We definitely do not want such different data items to appear the same.

Conclusion? It is nice to have a special data type that can record the limits of an interval with arbitrarily variable precision. Variable in the sense that each data element records its own precision.

Check this out:

```
test=> select '6.25 .. 6.50'::seg as "pH";
pH
-----
6.25 .. 6.50
(1 row)
```

## F.65.2. Syntax

The external representation of an interval is formed using one or two floating-point numbers joined by the range operator (`..` or `...`). Alternatively, it can be specified as a center point plus or minus a deviation. Optional certainty indicators (`<`, `>` or `~`) can be stored as well. (Certainty indicators are ignored by all the built-in operators, however.) [Table F.48](#) gives an overview of allowed representations; [Table F.49](#) shows some examples.

In [Table F.48](#), *x*, *y*, and *delta* denote floating-point numbers. *x* and *y*, but not *delta*, can be preceded by a certainty indicator.

**Table F.48. `seg` External Representations**

|                            |                                                                  |
|----------------------------|------------------------------------------------------------------|
| <i>x</i>                   | Single value (zero-length interval)                              |
| <i>x</i> .. <i>y</i>       | Interval from <i>x</i> to <i>y</i>                               |
| <i>x</i> (+-) <i>delta</i> | Interval from <i>x</i> - <i>delta</i> to <i>x</i> + <i>delta</i> |
| <i>x</i> ..                | Open interval with lower bound <i>x</i>                          |
| .. <i>x</i>                | Open interval with upper bound <i>x</i>                          |

**Table F.49. Examples of Valid `seg` Input**

|            |                                                                                                                                      |
|------------|--------------------------------------------------------------------------------------------------------------------------------------|
| 5.0        | Creates a zero-length segment (a point, if you will)                                                                                 |
| ~5.0       | Creates a zero-length segment and records ~ in the data. ~ is ignored by <code>seg</code> operations, but is preserved as a comment. |
| <5.0       | Creates a point at 5.0. < is ignored but is preserved as a comment.                                                                  |
| >5.0       | Creates a point at 5.0. > is ignored but is preserved as a comment.                                                                  |
| 5 (+-) 0.3 | Creates an interval 4.7 .. 5.3. Note that the (+-) notation isn't preserved.                                                         |

|                |                                                                                      |
|----------------|--------------------------------------------------------------------------------------|
| 50 ..          | Everything that is greater than or equal to 50                                       |
| .. 0           | Everything that is less than or equal to 0                                           |
| 1.5e-2 .. 2E-2 | Creates an interval 0.015 .. 0.02                                                    |
| 1 ... 2        | The same as 1...2, or 1 .. 2, or 1..2 (spaces around the range operator are ignored) |

Because the ... operator is widely used in data sources, it is allowed as an alternative spelling of the .. operator. Unfortunately, this creates a parsing ambiguity: it is not clear whether the upper bound in 0...23 is meant to be 23 or 0.23. This is resolved by requiring at least one digit before the decimal point in all numbers in `seg` input.

As a sanity check, `seg` rejects intervals with the lower bound greater than the upper, for example 5 .. 2.

### F.65.3. Precision

`seg` values are stored internally as pairs of 32-bit floating point numbers. This means that numbers with more than 7 significant digits will be truncated.

Numbers with 7 or fewer significant digits retain their original precision. That is, if your query returns 0.00, you will be sure that the trailing zeroes are not the artifacts of formatting: they reflect the precision of the original data. The number of leading zeroes does not affect precision: the value 0.0067 is considered to have just 2 significant digits.

### F.65.4. Usage

The `seg` module includes a GiST index operator class for `seg` values. The operators supported by the GiST operator class are shown in [Table F.50](#).

**Table F.50. Seg GiST Operators**

| Operator                                  | Description                                                                                                                                     |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>seg &lt;&lt; seg → boolean</code>   | Is the first <code>seg</code> entirely to the left of the second? <code>[a, b] &lt;&lt; [c, d]</code> is true if <code>b &lt; c</code> .        |
| <code>seg &gt;&gt; seg → boolean</code>   | Is the first <code>seg</code> entirely to the right of the second? <code>[a, b] &gt;&gt; [c, d]</code> is true if <code>a &gt; d</code> .       |
| <code>seg &amp;&lt; seg → boolean</code>  | Does the first <code>seg</code> not extend to the right of the second? <code>[a, b] &amp;&lt; [c, d]</code> is true if <code>b &lt;= d</code> . |
| <code>seg &amp;&gt; seg → boolean</code>  | Does the first <code>seg</code> not extend to the left of the second? <code>[a, b] &amp;&gt; [c, d]</code> is true if <code>a &gt;= c</code> .  |
| <code>seg = seg → boolean</code>          | Are the two <code>segs</code> equal?                                                                                                            |
| <code>seg &amp;&amp; seg → boolean</code> | Do the two <code>segs</code> overlap?                                                                                                           |
| <code>seg @&gt; seg → boolean</code>      | Does the first <code>seg</code> contain the second?                                                                                             |
| <code>seg &lt;@ seg → boolean</code>      | Is the first <code>seg</code> contained in the second?                                                                                          |

In addition to the above operators, the usual comparison operators shown in [Table 9.1](#) are available for type `seg`. These operators first compare (a) to (c), and if these are equal, compare (b) to (d). That results in reasonably good sorting in most cases, which is useful if you want to use ORDER BY with this type.

## F.65.5. Notes

For examples of usage, see the regression test `sql/seg.sql`.

The mechanism that converts `(+-)` to regular ranges isn't completely accurate in determining the number of significant digits for the boundaries. For example, it adds an extra digit to the lower boundary if the resulting interval includes a power of ten:

```
postgres=> select '10(+-)1'::seg as seg;
           seg
-----
9.0 .. 11          -- should be: 9 .. 11
```

The performance of an R-tree index can largely depend on the initial order of input values. It may be very helpful to sort the input table on the `seg` column; see the script `sort-segments.pl` for an example.

## F.65.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (<https://dsf.berkeley.edu/jmh/>) for elucidating the gist of the GiST (<http://gist.cs.berkeley.edu/>). I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

## F.66. shared\_ispell

The `shared_ispell` module provides a shared ispell dictionary, i.e. a dictionary that's stored in shared segment. The traditional ispell implementation means that each session initializes and stores the dictionary on it's own, which means a lot of CPU/RAM is wasted.

This extension allocates an area in shared segment (you have to choose the size in advance) and then loads the dictionary into it when it's used for the first time.

### F.66.1. Functions

The functions provided by the `shared_ispell` module are shown in [Table F.51](#).

**Table F.51. `shared_ispell` Functions**

| Function                                   | Returns                                                                                      | Description                                                                                                                                                            |
|--------------------------------------------|----------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>shared_ispell_reset()</code>         | void                                                                                         | Resets the dictionaries (e.g. so that you can reload the updated files from disk). The sessions that already use the dictionaries will be forced to reinitialize them. |
| <code>shared_ispell_mem_used()</code>      | int                                                                                          | Returns a value of used memory of the shared segment by loaded shared dictionaries in bytes.                                                                           |
| <code>shared_ispell_mem_available()</code> | int                                                                                          | Returns a value of available memory of the shared segment.                                                                                                             |
| <code>shared_ispell_dicts()</code>         | <code>setof(dict_name varchar, affix_name varchar, words int, affixes int, bytes int)</code> | Returns a list of dictionaries loaded in the shared segment.                                                                                                           |
| <code>shared_ispell_stoplists()</code>     | <code>setof(stop_name varchar, words int, bytes int)</code>                                  | Returns a list of stopwords loaded in the shared segment.                                                                                                              |

## F.66.2. GUC Parameters

`shared_ispell.max_size (int)`

Defines the maximum size of the shared segment. This is a hard limit, the shared segment is not extensible and you need to set it so that all the dictionaries fit into it and not much memory is wasted.

## F.66.3. Using the dictionary

The module needs to allocate space in the shared memory segment. So add this to the config file (or update the current values):

```
# libraries to load
shared_preload_libraries = 'shared_ispell'

# config of the shared memory
shared_ispell.max_size = 32MB
```

To find out how much memory you actually need, use a large value (e.g. 200MB) and load all the dictionaries you want to use. Then use the `shared_ispell_mem_used()` function to find out how much memory was actually used (and set the `shared_ispell.max_size` GUC variable accordingly).

Don't set it exactly to that value, leave there some free space, so that you can reload the dictionaries without changing the GUC `max_size` limit (which requires a restart of the DB). Something like 512kB should be just fine.

The extension defines a `shared_ispell` template that you may use to define custom dictionaries. E.g. you may do this:

```
CREATE TEXT SEARCH DICTIONARY english_shared (
    TEMPLATE = shared_ispell,
    DictFile = en_us,
    AffFile = en_us,
    StopWords = english
);

CREATE TEXT SEARCH CONFIGURATION public.english_shared
( COPY = pg_catalog.simple );

ALTER TEXT SEARCH CONFIGURATION english_shared
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
                        word, hword, hword_part
    WITH english_shared, english_stem;
```

We can test created configuration:

```
SELECT * FROM ts_debug('english_shared', 'abilities');
 alias | description | token | dictionaries | dictionary
-----+-----+-----+-----+-----
 asciiword | Word, all ASCII | abilities | {english_shared,english_stem} | english_shared | {ability}
(1 row)
```

Or you can update your own text search configuration. For example, you have the `public.english` dictionary. You can update it to use the `shared_ispell` template:

```
ALTER TEXT SEARCH CONFIGURATION public.english
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
                        word, hword, hword_part
```

## F.67. spi

The spi module provides several workable examples of using the [Server Programming Interface](#) (SPI) and triggers. While these functions are of some value in their own right, they are even more useful as examples to modify for your own purposes. The functions are general enough to be used with any table, but you have to specify table and field names (as described below) while creating a trigger.

Each of the groups of functions described below is provided as a separately-installable extension.

### F.67.1. refint — Functions for Implementing Referential Integrity

`check_primary_key()` and `check_foreign_key()` are used to check foreign key constraints. (This functionality is long since superseded by the built-in foreign key mechanism, of course, but the module is still useful as an example.)

`check_primary_key()` checks the referencing table. To use, create a `BEFORE INSERT OR UPDATE` trigger using this function on a table referencing another table. Specify as the trigger arguments: the referencing table's column name(s) which form the foreign key, the referenced table name, and the column names in the referenced table which form the primary/unique key. To handle multiple foreign keys, create a trigger for each reference.

`check_foreign_key()` checks the referenced table. To use, create a `BEFORE DELETE OR UPDATE` trigger using this function on a table referenced by other table(s). Specify as the trigger arguments: the number of referencing tables for which the function has to perform checking, the action if a referencing key is found (`cascade` — to delete the referencing row, `restrict` — to abort transaction if referencing keys exist, `setnull` — to set referencing key fields to null), the triggered table's column names which form the primary/unique key, then the referencing table name and column names (repeated for as many referencing tables as were specified by first argument). Note that the primary/unique key columns should be marked `NOT NULL` and should have a unique index.

There are examples in `refint.example`.

### F.67.2. autoinc — Functions for Autoincrementing Fields

`autoinc()` is a trigger that stores the next value of a sequence into an integer field. This has some overlap with the built-in “serial column” feature, but it is not the same: `autoinc()` will override attempts to substitute a different field value during inserts, and optionally it can be used to increment the field during updates, too.

To use, create a `BEFORE INSERT` (or optionally `BEFORE INSERT OR UPDATE`) trigger using this function. Specify two trigger arguments: the name of the integer column to be modified, and the name of the sequence object that will supply values. (Actually, you can specify any number of pairs of such names, if you'd like to update more than one autoincrementing column.)

There is an example in `autoinc.example`.

### F.67.3. insert\_username — Functions for Tracking Who Changed a Table

`insert_username()` is a trigger that stores the current user's name into a text field. This can be useful for tracking who last modified a particular row within a table.

To use, create a `BEFORE INSERT` and/or `UPDATE` trigger using this function. Specify a single trigger argument: the name of the text column to be modified.

There is an example in `insert_username.example`.

## F.67.4. moddatetime — Functions for Tracking Last Modification Time

`moddatetime()` is a trigger that stores the current time into a `timestamp` field. This can be useful for tracking the last modification time of a particular row within a table.

To use, create a `BEFORE UPDATE` trigger using this function. Specify a single trigger argument: the name of the column to be modified. The column must be of type `timestamp` or `timestamp with time zone`.

There is an example in `moddatetime.example`.

## F.68. sslinfo

The `sslinfo` module provides information about the SSL certificate that the current client provided when connecting to Postgres Pro. The module is useless (most functions will return `NULL`) if the current connection does not use SSL.

Some of the information available through this module can also be obtained using the built-in system view `pg_stat_ssl`.

This extension won't build at all unless the installation was configured with `--with-ssl=openssl`.

### F.68.1. Functions Provided

`ssl_is_used()` returns boolean

Returns true if current connection to server uses SSL, and false otherwise.

`ssl_version()` returns text

Returns the name of the protocol used for the SSL connection (e.g., TLSv1.0, TLSv1.1, TLSv1.2 or TLSv1.3).

`ssl_cipher()` returns text

Returns the name of the cipher used for the SSL connection (e.g., DHE-RSA-AES256-SHA).

`ssl_client_cert_present()` returns boolean

Returns true if current client has presented a valid SSL client certificate to the server, and false otherwise. (The server might or might not be configured to require a client certificate.)

`ssl_client_serial()` returns numeric

Returns serial number of current client certificate. The combination of certificate serial number and certificate issuer is guaranteed to uniquely identify a certificate (but not its owner — the owner ought to regularly change their keys, and get new certificates from the issuer).

So, if you run your own CA and allow only certificates from this CA to be accepted by the server, the serial number is the most reliable (albeit not very mnemonic) means to identify a user.

`ssl_client_dn()` returns text

Returns the full subject of the current client certificate, converting character data into the current database encoding. It is assumed that if you use non-ASCII characters in the certificate names, your database is able to represent these characters, too. If your database uses the `SQL_ASCII` encoding, non-ASCII characters in the name will be represented as UTF-8 sequences.

The result looks like `/CN=Somebody /C=Some country/O=Some organization`.

`ssl_issuer_dn()` returns text

Returns the full issuer name of the current client certificate, converting character data into the current database encoding. Encoding conversions are handled the same as for `ssl_client_dn`.

The combination of the return value of this function with the certificate serial number uniquely identifies the certificate.

This function is really useful only if you have more than one trusted CA certificate in your server's certificate authority file, or if this CA has issued some intermediate certificate authority certificates.

`ssl_client_dn_field(fieldname text)` returns text

This function returns the value of the specified field in the certificate subject, or NULL if the field is not present. Field names are string constants that are converted into ASN1 object identifiers using the OpenSSL object database. The following values are acceptable:

```
commonName (alias CN)
surname (alias SN)
name
givenName (alias GN)
countryName (alias C)
localityName (alias L)
stateOrProvinceName (alias ST)
organizationName (alias O)
organizationalUnitName (alias OU)
title
description
initials
postalCode
streetAddress
generationQualifier
description
dnQualifier
x500UniqueIdentifier
pseudonym
role
emailAddress
```

All of these fields are optional, except `commonName`. It depends entirely on your CA's policy which of them would be included and which wouldn't. The meaning of these fields, however, is strictly defined by the X.500 and X.509 standards, so you cannot just assign arbitrary meaning to them.

`ssl_issuer_field(fieldname text)` returns text

Same as `ssl_client_dn_field`, but for the certificate issuer rather than the certificate subject.

`ssl_extension_info()` returns setof record

Provide information about extensions of client certificate: extension name, extension value, and if it is a critical extension.

Dmitry Voronin <carriingfate92@yandex.ru>

E-Mail of Cryptocom OpenSSL development group: <openssl@cryptocom.ru>

## F.69. tablefunc

The `tablefunc` module includes various functions that return tables (that is, multiple rows). These functions are useful both in their own right and as examples of how to write C functions that return multiple rows.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

## F.69.1. Functions Provided

Table F.52 summarizes the functions provided by the `tablefunc` module.

**Table F.52. `tablefunc` Functions**

| Function                                                                                                                                                                       | Description                                                                                                                                                                                                                                                |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>normal_rand ( numvals integer, mean float8, stddev float8 ) → setof float8</code>                                                                                        | Produces a set of normally distributed random values.                                                                                                                                                                                                      |
| <code>crosstab ( sql text ) → setof record</code>                                                                                                                              | Produces a “pivot table” containing row names plus <i>N</i> value columns, where <i>N</i> is determined by the row type specified in the calling query.                                                                                                    |
| <code>crosstabN ( sql text ) → setof table_crosstab_ N</code>                                                                                                                  | Produces a “pivot table” containing row names plus <i>N</i> value columns. <code>crosstab2</code> , <code>crosstab3</code> , and <code>crosstab4</code> are predefined, but you can create additional <code>crosstabN</code> functions as described below. |
| <code>crosstab ( source_sql text, category_sql text ) → setof record</code>                                                                                                    | Produces a “pivot table” with the value columns specified by a second query.                                                                                                                                                                               |
| <code>crosstab ( sql text, N integer ) → setof record</code>                                                                                                                   | Obsolete version of <code>crosstab(text)</code> . The parameter <i>N</i> is now ignored, since the number of value columns is always determined by the calling query.                                                                                      |
| <code>connectby ( relname text, keyid_fld text, parent_keyid_fld text [, orderby_fld text ], start_with text, max_depth integer [, branch_delim text ] ) → setof record</code> | Produces a representation of a hierarchical tree structure.                                                                                                                                                                                                |

### F.69.1.1. `normal_rand`

`normal_rand(int numvals, float8 mean, float8 stddev)` returns `setof float8`

`normal_rand` produces a set of normally distributed random values (Gaussian distribution).

*numvals* is the number of values to be returned from the function. *mean* is the mean of the normal distribution of values and *stddev* is the standard deviation of the normal distribution of values.

For example, this call requests 1000 values with a mean of 5 and a standard deviation of 3:

```
test=# SELECT * FROM normal_rand(1000, 5, 3);
normal_rand
```

```

```

2.49639286969028

(1000 rows)

### F.69.1.2. `crosstab(text)`

```
crosstab(text sql)
crosstab(text sql, int N)
```

The `crosstab` function is used to produce “pivot” displays, wherein data is listed across the page rather than down. For example, we might have data like

```
row1    val11
row1    val12
row1    val13
...
row2    val21
row2    val22
row2    val23
...
```

which we wish to display like

```
row1    val11    val12    val13    ...
row2    val21    val22    val23    ...
...
```

The `crosstab` function takes a text parameter that is an SQL query producing raw data formatted in the first way, and produces a table formatted in the second way.

The `sql` parameter is an SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. `N` is an obsolete parameter, ignored if supplied (formerly this had to match the number of output value columns, but now that is determined by the calling query).

For example, the provided query might produce a set something like:

| row_name | cat  | value |
|----------|------|-------|
| row1     | cat1 | val1  |
| row1     | cat2 | val2  |
| row1     | cat3 | val3  |
| row1     | cat4 | val4  |
| row2     | cat1 | val5  |
| row2     | cat2 | val6  |
| row2     | cat3 | val7  |
| row2     | cat4 | val8  |

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...') AS ct(row_name text, category_1 text, category_2 text);
```

This example produces a set something like:

|          | <== value columns ==> |            |
|----------|-----------------------|------------|
| row_name | category_1            | category_2 |
| row1     | val1                  | val2       |
| row2     | val5                  | val6       |

The `FROM` clause must define the output as one `row_name` column (of the same data type as the first result column of the SQL query) followed by `N` `value` columns (all of the same data type as the third result column of the SQL query). You can set up as many output value columns as you wish. The names of the output columns are up to you.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. It fills the output `value` columns, left to right, with the `value` fields from these rows. If there are fewer rows in a group than there are output `value` columns, the extra output columns are filled with nulls; if there are more rows, the extra input rows are skipped.

In practice the SQL query should always specify `ORDER BY 1,2` to ensure that the input rows are properly ordered, that is, values with the same `row_name` are brought together and correctly ordered within the row. Notice that `crosstab` itself does not pay any attention to the second column of the query result; it's just there to be ordered by, to control the order in which the third-column values appear across the page.

Here is a complete example:

```
CREATE TABLE ct(id SERIAL, rowid TEXT, attribute TEXT, value TEXT);
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att1','val1');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att2','val2');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att3','val3');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att4','val4');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att1','val5');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att2','val6');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att3','val7');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att4','val8');

SELECT *
FROM crosstab(
    'select rowid, attribute, value
    from ct
    where attribute = ''att2'' or attribute = ''att3''
    order by 1,2')
AS ct(row_name text, category_1 text, category_2 text, category_3 text);

 row_name | category_1 | category_2 | category_3
-----+-----+-----+-----
 test1    | val2       | val3       |
 test2    | val6       | val7       |
(2 rows)
```

You can avoid always having to write out a `FROM` clause to define the output columns, by setting up a custom `crosstab` function that has the desired output row type wired into its definition. This is described in the next section. Another possibility is to embed the required `FROM` clause in a view definition.

## Note

See also the `\crosstabview` command in `psql`, which provides functionality similar to `crosstab()`.

### F.69.1.3. `crosstabN(text)`

```
crosstabN(text sql)
```

The `crosstabN` functions are examples of how to set up custom wrappers for the general `crosstab` function, so that you need not write out column names and types in the calling `SELECT` query. The `tablefunc` module includes `crosstab2`, `crosstab3`, and `crosstab4`, whose output row types are defined as

```
CREATE TYPE tablefunc_crosstab_N AS (
    row_name TEXT,
    category_1 TEXT,
    category_2 TEXT,
    .
    .
    .
```

```
category_N TEXT  
);
```

Thus, these functions can be used directly when the input query produces `row_name` and `value` columns of type `text`, and you want 2, 3, or 4 output values columns. In all other ways they behave exactly as described above for the general `crosstab` function.

For instance, the example given in the previous section would also work as

```
SELECT *  
FROM crosstab3(  
  'select rowid, attribute, value  
   from ct  
   where attribute = 'att2' or attribute = 'att3'  
   order by 1,2');
```

These functions are provided mostly for illustration purposes. You can create your own return types and functions based on the underlying `crosstab()` function. There are two ways to do it:

- Create a composite type describing the desired output columns, similar to the examples in `contrib/tablefunc/tablefunc--1.0.sql`. Then define a unique function name accepting one `text` parameter and returning `setof your_type_name`, but linking to the same underlying `crosstab C` function. For example, if your source data produces row names that are `text`, and values that are `float8`, and you want 5 value columns:

```
CREATE TYPE my_crosstab_float8_5_cols AS (  
  my_row_name text,  
  my_category_1 float8,  
  my_category_2 float8,  
  my_category_3 float8,  
  my_category_4 float8,  
  my_category_5 float8  
);  
  
CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(text)  
  RETURNS setof my_crosstab_float8_5_cols  
  AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;
```

- Use `OUT` parameters to define the return type implicitly. The same example could also be done this way:

```
CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(  
  IN text,  
  OUT my_row_name text,  
  OUT my_category_1 float8,  
  OUT my_category_2 float8,  
  OUT my_category_3 float8,  
  OUT my_category_4 float8,  
  OUT my_category_5 float8)  
  RETURNS setof record  
  AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;
```

#### F.69.1.4. `crosstab(text, text)`

```
crosstab(text source_sql, text category_sql)
```

The main limitation of the single-parameter form of `crosstab` is that it treats all values in a group alike, inserting each value into the first available column. If you want the value columns to correspond to specific categories of data, and some groups might not have data for some of the categories, that doesn't work well. The two-parameter form of `crosstab` handles this case by providing an explicit list of the categories corresponding to the output columns.

Additional Supplied Modules  
and Extensions Shipped in  
postgrespro-ent-14-contrib

*source\_sql* is an SQL statement that produces the source set of data. This statement must return one *row\_name* column, one *category* column, and one *value* column. It may also have one or more “extra” columns. The *row\_name* column must be first. The *category* and *value* columns must be the last two columns, in that order. Any columns between *row\_name* and *category* are treated as “extra”. The “extra” columns are expected to be the same for all rows with the same *row\_name* value.

For example, *source\_sql* might produce a set something like:

```
SELECT row_name, extra_col, cat, value FROM foo ORDER BY 1;
```

| row_name | extra_col | cat  | value |
|----------|-----------|------|-------|
| row1     | extra1    | cat1 | val1  |
| row1     | extra1    | cat2 | val2  |
| row1     | extra1    | cat4 | val4  |
| row2     | extra2    | cat1 | val5  |
| row2     | extra2    | cat2 | val6  |
| row2     | extra2    | cat3 | val7  |
| row2     | extra2    | cat4 | val8  |

*category\_sql* is an SQL statement that produces the set of categories. This statement must return only one column. It must produce at least one row, or an error will be generated. Also, it must not produce duplicate values, or an error will be generated. *category\_sql* might be something like:

```
SELECT DISTINCT cat FROM foo ORDER BY 1;
cat
-----
cat1
cat2
cat3
cat4
```

The *crosstab* function is declared to return *setof record*, so the actual names and types of the output columns must be defined in the *FROM* clause of the calling *SELECT* statement, for example:

```
SELECT * FROM crosstab('...', '...')
AS ct(row_name text, extra text, cat1 text, cat2 text, cat3 text, cat4 text);
```

This will produce a result something like:

|          |        | <== value columns ==> |      |      |      |
|----------|--------|-----------------------|------|------|------|
| row_name | extra  | cat1                  | cat2 | cat3 | cat4 |
| row1     | extra1 | val1                  | val2 |      | val4 |
| row2     | extra2 | val5                  | val6 | val7 | val8 |

The *FROM* clause must define the proper number of output columns of the proper data types. If there are *N* columns in the *source\_sql* query's result, the first *N-2* of them must match up with the first *N-2* output columns. The remaining output columns must have the type of the last column of the *source\_sql* query's result, and there must be exactly as many of them as there are rows in the *category\_sql* query's result.

The *crosstab* function produces one output row for each consecutive group of input rows with the same *row\_name* value. The output *row\_name* column, plus any “extra” columns, are copied from the first row of the group. The output *value* columns are filled with the *value* fields from rows having matching category values. If a row's *category* does not match any output of the *category\_sql* query, its *value* is ignored. Output columns whose matching category is not present in any input row of the group are filled with nulls.

In practice the *source\_sql* query should always specify *ORDER BY 1* to ensure that values with the same *row\_name* are brought together. However, ordering of the categories within a group is not important.

Also, it is essential to be sure that the order of the *category\_sql* query's output matches the specified output column order.

Here are two complete examples:

```
create table sales(year int, month int, qty int);
insert into sales values(2007, 1, 1000);
insert into sales values(2007, 2, 1500);
insert into sales values(2007, 7, 500);
insert into sales values(2007, 11, 1500);
insert into sales values(2007, 12, 2000);
insert into sales values(2008, 1, 1000);
```

```
select * from crosstab(
    'select year, month, qty from sales order by 1',
    'select m from generate_series(1,12) m'
```

```
) as (
```

```
year int,
"Jan" int,
"Feb" int,
"Mar" int,
"Apr" int,
"May" int,
"Jun" int,
"Jul" int,
"Aug" int,
"Sep" int,
"Oct" int,
"Nov" int,
"Dec" int
```

```
);
```

| year | Jan  | Feb  | Mar | Apr | May | Jun | Jul | Aug | Sep | Oct | Nov  | Dec  |
|------|------|------|-----|-----|-----|-----|-----|-----|-----|-----|------|------|
| 2007 | 1000 | 1500 |     |     |     |     | 500 |     |     |     | 1500 | 2000 |
| 2008 | 1000 |      |     |     |     |     |     |     |     |     |      |      |

```
(2 rows)
```

```
CREATE TABLE cth(rowid text, rowdt timestamp, attribute text, val text);
INSERT INTO cth VALUES('test1','01 March 2003','temperature','42');
INSERT INTO cth VALUES('test1','01 March 2003','test_result','PASS');
INSERT INTO cth VALUES('test1','01 March 2003','volts','2.6987');
INSERT INTO cth VALUES('test2','02 March 2003','temperature','53');
INSERT INTO cth VALUES('test2','02 March 2003','test_result','FAIL');
INSERT INTO cth VALUES('test2','02 March 2003','test_startdate','01 March 2003');
INSERT INTO cth VALUES('test2','02 March 2003','volts','3.1234');
```

```
SELECT * FROM crosstab
```

```
(
    'SELECT rowid, rowdt, attribute, val FROM cth ORDER BY 1',
    'SELECT DISTINCT attribute FROM cth ORDER BY 1'
```

```
)
```

```
AS
```

```
(
    rowid text,
    rowdt timestamp,
    temperature int4,
    test_result text,
    test_startdate timestamp,
    volts float8
```

```
);
rowid |          rowdt          | temperature | test_result |          test_startdate
| volts
-----+-----+-----+-----+-----
test1 | Sat Mar 01 00:00:00 2003 |          42 | PASS        |
| 2.6987
test2 | Sun Mar 02 00:00:00 2003 |          53 | FAIL        | Sat Mar 01 00:00:00
2003 | 3.1234
(2 rows)
```

You can create predefined functions to avoid having to write out the result column names and types in each query. See the examples in the previous section. The underlying C function for this form of `crosstab` is named `crosstab_hash`.

### F.69.1.5. connectby

```
connectby(text relname, text keyid_fld, text parent_keyid_fld
          [, text orderby_fld ], text start_with, int max_depth
          [, text branch_delim ])
```

The `connectby` function produces a display of hierarchical data that is stored in a table. The table must have a key field that uniquely identifies rows, and a parent-key field that references the parent (if any) of each row. `connectby` can display the sub-tree descending from any row.

Table F.53 explains the parameters.

**Table F.53. connectby Parameters**

| Parameter               | Description                                              |
|-------------------------|----------------------------------------------------------|
| <i>relname</i>          | Name of the source relation                              |
| <i>keyid_fld</i>        | Name of the key field                                    |
| <i>parent_keyid_fld</i> | Name of the parent-key field                             |
| <i>orderby_fld</i>      | Name of the field to order siblings by (optional)        |
| <i>start_with</i>       | Key value of the row to start at                         |
| <i>max_depth</i>        | Maximum depth to descend to, or zero for unlimited depth |
| <i>branch_delim</i>     | String to separate keys with in branch output (optional) |

The key and parent-key fields can be any data type, but they must be the same type. Note that the *start\_with* value must be entered as a text string, regardless of the type of the key field.

The `connectby` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0,
    '~')
    AS t(keyid text, parent_keyid text, level int, branch text, pos int);
```

The first two output columns are used for the current row's key and its parent row's key; they must match the type of the table's key field. The third output column is the depth in the tree and must be of type `integer`. If a *branch\_delim* parameter was given, the next output column is the branch display and must be of type `text`. Finally, if an *orderby\_fld* parameter was given, the last output column is a serial number, and must be of type `integer`.

The “branch” output column shows the path of keys taken to reach the current row. The keys are separated by the specified *branch\_delim* string. If no branch display is wanted, omit both the *branch\_delim* parameter and the branch column in the output column list.

If the ordering of siblings of the same parent is important, include the `orderby_fld` parameter to specify which field to order siblings by. This field can be of any sortable data type. The output column list must include a final integer serial-number column, if and only if `orderby_fld` is specified.

The parameters representing table and field names are copied as-is into the SQL queries that `connectby` generates internally. Therefore, include double quotes if the names are mixed-case or contain special characters. You may also need to schema-qualify the table name.

In large tables, performance will be poor unless there is an index on the parent-key field.

It is important that the `branch_delim` string not appear in any key values, else `connectby` may incorrectly report an infinite-recursion error. Note that if `branch_delim` is not provided, a default value of `~` is used for recursion detection purposes.

Here is an example:

```
CREATE TABLE connectby_tree(keyid text, parent_keyid text, pos int);
```

```
INSERT INTO connectby_tree VALUES('row1',NULL, 0);
INSERT INTO connectby_tree VALUES('row2','row1', 0);
INSERT INTO connectby_tree VALUES('row3','row1', 0);
INSERT INTO connectby_tree VALUES('row4','row2', 1);
INSERT INTO connectby_tree VALUES('row5','row2', 0);
INSERT INTO connectby_tree VALUES('row6','row4', 0);
INSERT INTO connectby_tree VALUES('row7','row3', 0);
INSERT INTO connectby_tree VALUES('row8','row6', 0);
INSERT INTO connectby_tree VALUES('row9','row5', 0);
```

```
-- with branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0, '~')
AS t(keyid text, parent_keyid text, level int, branch text);
```

| keyid | parent_keyid | level | branch              |
|-------|--------------|-------|---------------------|
| row2  |              | 0     | row2                |
| row4  | row2         | 1     | row2~row4           |
| row6  | row4         | 2     | row2~row4~row6      |
| row8  | row6         | 3     | row2~row4~row6~row8 |
| row5  | row2         | 1     | row2~row5           |
| row9  | row5         | 2     | row2~row5~row9      |

(6 rows)

```
-- without branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0)
AS t(keyid text, parent_keyid text, level int);
```

| keyid | parent_keyid | level |
|-------|--------------|-------|
| row2  |              | 0     |
| row4  | row2         | 1     |
| row6  | row4         | 2     |
| row8  | row6         | 3     |
| row5  | row2         | 1     |
| row9  | row5         | 2     |

(6 rows)

```
-- with branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0,
 '~')
AS t(keyid text, parent_keyid text, level int, branch text, pos int);
```

| keyid | parent_keyid | level | branch              | pos |
|-------|--------------|-------|---------------------|-----|
| row2  |              | 0     | row2                | 0   |
| row5  | row2         | 1     | row2~row5           | 1   |
| row4  | row2         | 1     | row2~row4           | 2   |
| row6  | row4         | 2     | row2~row4~row6      | 3   |
| row8  | row6         | 3     | row2~row4~row6~row8 | 4   |
| row9  | row5         | 2     | row2~row5~row9      | 5   |

## F.69.2. Author

Joe Conway

## F.70. tcn

The `tcn` module provides a trigger function that notifies listeners of changes to any table on which it is attached. It must be used as an `AFTER trigger FOR EACH ROW`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

Only one parameter may be supplied to the function in a `CREATE TRIGGER` statement, and that is optional. If supplied it will be used for the channel name for the notifications. If omitted `tcn` will be used for the channel name.

The payload of the notifications consists of the table name, a letter to indicate which type of operation was performed, and column name/value pairs for primary key columns. Each part is separated from the next by a comma. For ease of parsing using regular expressions, table and column names are always wrapped in double quotes, and data values are always wrapped in single quotes. Embedded quotes are doubled.

A brief example of using the extension follows.

```
test=# create table tcndata
test=# (
test(#   a int not null,
test(#   b date not null,
test(#   c text,
test(#   primary key (a, b)
test(# );
CREATE TABLE
test=# create trigger tcndata_tcn_trigger
test=#   after insert or update or delete on tcndata
test=#   for each row execute function triggered_change_notification();
CREATE TRIGGER
test=# listen tcn;
LISTEN
```

## Additional Supplied Modules and Extensions Shipped in postgrespro-ent-14-contrib

---

```

test=# insert into tcndata values (1, date '2012-12-22', 'one'),
test=#                               (1, date '2012-12-23', 'another'),
test=#                               (2, date '2012-12-23', 'two');
INSERT 0 3
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='1',"b"='2012-12-22'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='1',"b"='2012-12-23'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='2',"b"='2012-12-23'"
received from server process with PID 22770.
test=# update tcndata set c = 'uno' where a = 1;
UPDATE 2
Asynchronous notification "tcn" with payload ""tcndata",U,"a"='1',"b"='2012-12-22'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",U,"a"='1',"b"='2012-12-23'"
received from server process with PID 22770.
test=# delete from tcndata where a = 1 and b = date '2012-12-22';
DELETE 1
Asynchronous notification "tcn" with payload ""tcndata",D,"a"='1',"b"='2012-12-22'"
received from server process with PID 22770.

```

## F.71. test\_decoding

`test_decoding` is an example of a logical decoding output plugin. It doesn't do anything especially useful, but can serve as a starting point for developing your own output plugin.

`test_decoding` receives WAL through the logical decoding mechanism and decodes it into text representations of the operations performed.

Typical output from this plugin, used over the SQL logical decoding interface, might be:

```

postgres=# SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL, 'include-
xids', '0');
 location | xid | data
-----+-----+-----
 0/16D30F8 | 691 | BEGIN
 0/16D32A0 | 691 | table public.data: INSERT: id[int4]:2 data[text]:'arg'
 0/16D32A0 | 691 | table public.data: INSERT: id[int4]:3 data[text]:'demo'
 0/16D32A0 | 691 | COMMIT
 0/16D32D8 | 692 | BEGIN
 0/16D3398 | 692 | table public.data: DELETE: id[int4]:2
 0/16D3398 | 692 | table public.data: DELETE: id[int4]:3
 0/16D3398 | 692 | COMMIT
(8 rows)

```

We can also get the changes of the in-progress transaction, and the typical output might be:

```

postgres[33712]=# SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL,
'stream-changes', '1');
   lsn   | xid | data
-----+-----+-----
 0/16B21F8 | 503 | opening a streamed block for transaction TXN 503
 0/16B21F8 | 503 | streaming change for TXN 503
 0/16B2300 | 503 | streaming change for TXN 503
 0/16B2408 | 503 | streaming change for TXN 503
 0/16BEBA0 | 503 | closing a streamed block for transaction TXN 503
 0/16B21F8 | 503 | opening a streamed block for transaction TXN 503
 0/16BECA8 | 503 | streaming change for TXN 503
 0/16BEDB0 | 503 | streaming change for TXN 503
 0/16BEEB8 | 503 | streaming change for TXN 503

```

0/16BEBA0 | 503 | closing a streamed block for transaction TXN 503  
(10 rows)

## F.72. tsm\_system\_rows

The `tsm_system_rows` module provides the table sampling method `SYSTEM_ROWS`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single integer argument that is the maximum number of rows to read. The resulting sample will always contain exactly that many rows, unless the table does not contain enough rows, in which case the whole table is selected.

Like the built-in `SYSTEM` sampling method, `SYSTEM_ROWS` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are requested.

`SYSTEM_ROWS` does not support the `REPEATABLE` clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.72.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_ROWS`. First install the extension:

```
CREATE EXTENSION tsm_system_rows;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_ROWS(100);
```

This command will return a sample of 100 rows from the table `my_table` (unless the table does not have 100 visible rows, in which case all its rows are returned).

## F.73. tsm\_system\_time

The `tsm_system_time` module provides the table sampling method `SYSTEM_TIME`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single floating-point argument that is the maximum number of milliseconds to spend reading the table. This gives you direct control over how long the query takes, at the price that the size of the sample becomes hard to predict. The resulting sample will contain as many rows as could be read in the specified time, unless the whole table has been read first.

Like the built-in `SYSTEM` sampling method, `SYSTEM_TIME` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are selected.

`SYSTEM_TIME` does not support the `REPEATABLE` clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.73.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_TIME`. First install the extension:

```
CREATE EXTENSION tsm_system_time;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_TIME(1000);
```

This command will return as large a sample of `my_table` as it can read in 1 second (1000 milliseconds). Of course, if the whole table can be read in under 1 second, all its rows will be returned.

## F.74. unaccent

`unaccent` is a text search dictionary that removes accents (diacritic signs) from lexemes. It's a filtering dictionary, which means its output is always passed to the next dictionary (if any), unlike the normal behavior of dictionaries. This allows accent-insensitive processing for full text search.

The current implementation of `unaccent` cannot be used as a normalizing dictionary for the `thesaurus` dictionary.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.74.1. Configuration

An `unaccent` dictionary accepts the following options:

- `RULES` is the base name of the file containing the list of translation rules. This file must be stored in `$SHAREDIR/tsearch_data/` (where `$SHAREDIR` means the Postgres Pro installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `RULES` parameter).

The rules file has the following format:

- Each line represents one translation rule, consisting of a character with accent followed by a character without accent. The first is translated into the second. For example,

|   |    |
|---|----|
| À | A  |
| Á | A  |
| Â | A  |
| Ã | A  |
| Ä | A  |
| Å | A  |
| Æ | AE |

The two characters must be separated by whitespace, and any leading or trailing whitespace on a line is ignored.

- Alternatively, if only one character is given on a line, instances of that character are deleted; this is useful in languages where accents are represented by separate characters.
- Actually, each “character” can be any string not containing whitespace, so `unaccent` dictionaries could be used for other sorts of substring substitutions besides diacritic removal.
- As with other Postgres Pro text search configuration files, the rules file must be stored in UTF-8 encoding. The data is automatically translated into the current database's encoding when loaded. Any lines containing untranslatable characters are silently ignored, so that rules files can contain rules that are not applicable in the current encoding.

A more complete example, which is directly useful for most European languages, can be found in `unaccent.rules`, which is installed in `$SHAREDIR/tsearch_data/` when the `unaccent` module is installed. This rules file translates characters with accents to the same characters without accents, and it also expands ligatures into the equivalent series of simple characters (for example, `Æ` to `AE`).

### F.74.2. Usage

Installing the `unaccent` extension creates a text search template `unaccent` and a dictionary `unaccent` based on it. The `unaccent` dictionary has the default parameter setting `RULES='unaccent'`, which makes it immediately usable with the standard `unaccent.rules` file. If you wish, you can alter the parameter, for example

```
mydb=# ALTER TEXT SEARCH DICTIONARY unaccent (RULES='my_rules');
```

or create new dictionaries based on the template.

To test the dictionary, you can try:

```
mydb=# select ts_lexize('unaccent','Hôtel');
      ts_lexize
-----
 {Hotel}
(1 row)
```

Here is an example showing how to insert the `unaccent` dictionary into a text search configuration:

```
mydb=# CREATE TEXT SEARCH CONFIGURATION fr ( COPY = french );
mydb=# ALTER TEXT SEARCH CONFIGURATION fr
      ALTER MAPPING FOR hword, hword_part, word
      WITH unaccent, french_stem;
mydb=# select to_tsvector('fr','Hôtels de la Mer');
      to_tsvector
-----
 'hotel':1 'mer':4
(1 row)

mydb=# select to_tsvector('fr','Hôtel de la Mer') @@ to_tsquery('fr','Hotels');
      ?column?
-----
 t
(1 row)

mydb=# select ts_headline('fr','Hôtel de la Mer',to_tsquery('fr','Hotels'));
      ts_headline
-----
 <b>Hôtel</b> de la Mer
(1 row)
```

### F.74.3. Functions

The `unaccent()` function removes accents (diacritic signs) from a given string. Basically, it's a wrapper around `unaccent-type` dictionaries, but it can be used outside normal text search contexts.

`unaccent([dictionary regdictionary, ] string text)` returns *text*

If the *dictionary* argument is omitted, the text search dictionary named `unaccent` and appearing in the same schema as the `unaccent()` function itself is used.

For example:

```
SELECT unaccent('unaccent', 'Hôtel');
SELECT unaccent('Hôtel');
```

## F.75. uuid-oss

The `uuid-oss` module provides functions to generate universally unique identifiers (UUIDs) using one of several standard algorithms. There are also functions to produce certain special UUID constants. This module is only necessary for special requirements beyond what is available in core PostgreSQL. See [Section 9.14](#) for built-in ways to generate UUIDs.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.75.1. uuid-oss Functions

[Table F.54](#) shows the functions available to generate UUIDs. The relevant standards ITU-T Rec. X.667, ISO/IEC 9834-8:2005, and [RFC 4122](#) specify four algorithms for generating UUIDs, identified by the version numbers 1, 3, 4, and 5. (There is no version 2 algorithm.) Each of these algorithms could be suitable for a different set of applications.

**Table F.54. Functions for UUID Generation**

| Function                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>uuid_generate_v1 () → uuid</code>                            | Generates a version 1 UUID. This involves the MAC address of the computer and a time stamp. Note that UUIDs of this kind reveal the identity of the computer that created the identifier and the time at which it did so, which might make it unsuitable for certain security-sensitive applications.                                                                                                                                                                                                                                                                                                                                    |
| <code>uuid_generate_v1mc () → uuid</code>                          | Generates a version 1 UUID, but uses a random multicast MAC address instead of the real MAC address of the computer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>uuid_generate_v3 ( namespace uuid, name text ) → uuid</code> | Generates a version 3 UUID in the given namespace using the specified input name. The namespace should be one of the special constants produced by the <code>uuid_ns_*</code> () functions shown in Table F.55. (It could be any UUID in theory.) The name is an identifier in the selected namespace.<br>For example:<br><br><pre>SELECT uuid_generate_v3(uuid_ns_url(), 'http://www.postgresql.org');</pre><br>The name parameter will be MD5-hashed, so the cleartext cannot be derived from the generated UUID. The generation of UUIDs by this method has no random or environment-dependent element and is therefore reproducible. |
| <code>uuid_generate_v4 () → uuid</code>                            | Generates a version 4 UUID, which is derived entirely from random numbers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>uuid_generate_v5 ( namespace uuid, name text ) → uuid</code> | Generates a version 5 UUID, which works like a version 3 UUID except that SHA-1 is used as a hashing method. Version 5 should be preferred over version 3 because SHA-1 is thought to be more secure than MD5.                                                                                                                                                                                                                                                                                                                                                                                                                           |

**Table F.55. Functions Returning UUID Constants**

| Function                            | Description                                                                                                                                                              |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>uuid_nil () → uuid</code>     | Returns a “nil” UUID constant, which does not occur as a real UUID.                                                                                                      |
| <code>uuid_ns_dns () → uuid</code>  | Returns a constant designating the DNS namespace for UUIDs.                                                                                                              |
| <code>uuid_ns_url () → uuid</code>  | Returns a constant designating the URL namespace for UUIDs.                                                                                                              |
| <code>uuid_ns_oid () → uuid</code>  | Returns a constant designating the ISO object identifier (OID) namespace for UUIDs. (This pertains to ASN.1 OIDs, which are unrelated to the OIDs used in Postgres Pro.) |
| <code>uuid_ns_x500 () → uuid</code> | Returns a constant designating the X.500 distinguished name (DN) namespace for UUIDs.                                                                                    |

## F.75.2. Building `uuid-oss`

Historically this module depended on the OSSP UUID library, which accounts for the module's name. While the OSSP UUID library can still be found at <http://www.ossdp.org/pkg/lib/uuid/>, it is not well maintained, and is becoming increasingly difficult to port to newer platforms. `uuid-oss` can now be built without the OSSP library on some platforms. On FreeBSD and some other BSD-derived platforms, suitable UUID creation functions are included in the core `libc` library. On Linux, macOS, and some other

platforms, suitable functions are provided in the `libuuid` library, which originally came from the `e2fsprogs` project (though on modern Linux it is considered part of `util-linux-ng`). When invoking `configure`, specify `--with-uuid=bsd` to use the BSD functions, or `--with-uuid=e2fs` to use `e2fsprogs`' `libuuid`, or `--with-uuid=ossdp` to use the OSSP UUID library. More than one of these libraries might be available on a particular machine, so `configure` does not automatically choose one.

## F.76. vops

### Important

The `vops` extension is considered deprecated. It is not recommended to use it.

The `vops` module is an experimental Postgres Pro Enterprise extension that provides support for vector operations, which allows to speed up OLAP queries with filtering and aggregation more than 10 times. Performance improvements are achieved by implementing a vertical data model that allows storing data in *tiles*, or groups of column values. Such a storage format is also called *Parquet* in some analytical databases. Reducing the overhead of unpacking tuples, vertical data model allows to speed up query execution without any radical changes in Postgres Pro planner and executor.

`vops` provides its own set of vector functions that can be used inside predicates and aggregate expressions. To avoid learning new syntax, you can use `postgres_fdw` as an abstraction layer and run regular SQL queries on vectorized data. For query types other than filtering and aggregation, `vops` can also use `postgres_fdw` to present vectorized data as a regular table with scalar column types and process this data as regular tuples. For ease of use, `vops` also provides an automated way of generating and accessing vectorized data, as explained in [Section F.76.5.5](#).

### F.76.1. Limitations

- Tile-based tables only allow `INSERT` and `APPEND` operations. Once imported, vectorized data cannot be updated.
- Vector operations are only available for filtering and aggregation. Other query types are supported via `postgres_fdw`.
- Aggregate expressions must be of the same type.
- `JOIN` operations are not supported for vector types. You have to use `postgres_fdw` to transform vectorized data back to regular tuples to run such queries.
- Since `postgres_fdw` does not support parallel query execution, you can only run parallel queries when using vector operators directly.

### F.76.2. Installation and Setup

The `vops` extension is included into Postgres Pro Enterprise. Once you have Postgres Pro Enterprise installed, complete the following steps to enable `vops`:

1. Add `vops` to the [shared\\_preload\\_libraries](#) parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'vops'
```

### Note

If the extension library is not added to the `shared_preload_libraries` list, it will be loaded on demand after the first function invocation of this extension. In this case, the first time you execute a vectorized query, it will not be processed correctly and can return a wrong result.

2. Restart the Postgres Pro Enterprise instance for the changes to take effect.

3. Create `vops` extension:

```
CREATE EXTENSION vops;
```

Once `vops` is enabled, you can create vectorized tables and query data using vector operations in your database.

If you would like to use regular SQL syntax for vector types, you must also enable [postgres\\_fdw](#).

## F.76.3. Motivation

For OLTP workloads, Postgres Pro looks very competitive as compared to other mainstream databases. However, for OLAP queries, which require processing larger volumes of data, analytics-oriented database management systems can provide a much better speed. There are several main factors that limit Postgres Pro performance:

- **Tuple unpacking overhead.** To access column values, Postgres Pro needs to unpack the tuple. As tables can have columns of variable-length data types, to extract the N-th column, the preceding N-1 columns need to be unpacked. Thus, deforming a tuple is quite an expensive operation, especially for tables with a large number of attributes. Besides, values can be compressed or stored in another page (TOAST). In queries like Query 6 of the [TPC-H benchmark](#), deforming tuples takes about 40% of the total query execution time.
- **Interpretation overhead.** Postgres Pro planner and optimizer build a tree representing the query execution plan. Query executor recursively calls functions that evaluate the nodes of this tree. Some nodes may also contain switches used to select the requested action. Thus, query plan is interpreted by Postgres Pro query executor rather than directly executed. The interpreter is usually about 10 times slower than the native code. If you eliminate interpretation overhead, you can increase query speed several times, especially for queries with complex predicates that have high evaluation costs.
- **Abstraction penalty.** Support for abstract (user-defined) types and operations is one of the key features of Postgres Pro. However, the price of such flexibility is that each operation requires a separate function call. Instead of adding two integers directly, Postgres Pro executor invokes a function that performs addition. In this case, function call overhead is much higher than the cost the operation itself. Function call overhead is also increased because Postgres Pro requires passing parameter values through memory.
- **Pull model overhead.** In Postgres Pro, operators pull the operand values. This approach simplifies the implementation of operators and the executor, but has a negative impact on performance. In this model, leaf nodes that fetch a tuple from the heap or index pages have to do a lot of extra work while saving and restoring their context.
- **MVCC overhead.** Postgres Pro provides multi-version concurrency control, which allows multiple transactions to work with the same record in parallel without blocking each other. It is good for frequently updated data (OLTP), but for read-only or append-only data in OLAP scenarios it only adds both space overhead (about 20 extra bytes per tuple) and CPU overhead (checking visibility of each tuple).

Vector operations can address most of these issues without radical changes in the Postgres Pro executor, as explained in [Section F.76.4](#).

## F.76.4. Architecture

The `vops` extension implements a *vertical data model* for Postgres Pro. In this model, vertical columns are used as a data storing unit, with the values of the corresponding table attribute forming a vector.

The vertical data model used by `vops` has the following advantages:

- **Reduces the size of fetched data:** only the columns used in the query need to be fetched.
- **Achieves higher compression rates:** storing all values of the same attribute together makes it possible to compress them much better and faster. For example, you can use delta encoding.
- **Minimizes interpretation overhead:** a set of values can be processed by a single operation instead of running separate operations for each value.

- Uses CPU vector instructions (SIMD) to process data.

A traditional Postgres Pro query executor deals with a single row of data at each moment of time. For example, to evaluate an expression  $(x+y)$ , it first fetches the value of  $x$ , then fetches the value of  $y$ , performs the addition, and returns the result value to the upper node. In contrast, a vectorized executor can process multiple values within a single operation. In this case,  $x$  and  $y$  represent vectors of values instead of single scalars. The returned result is also a vector. In vector execution model, interpretation and function call overhead is divided by the vector size. The price of performing a function call is the same, but as the function processes  $N$  values instead of a single one, this overhead becomes less critical. The larger the vector, the smaller the per-row overhead.

However, performing an operation on the whole column may also turn out to be ineffective. Working with large vectors prevents efficient utilization of CPU cache levels. If the table is very large, the vector may not fit in memory at all. To avoid these issues, `vops` splits the columns into relatively small chunks, or *tiles*. The size of a tile is currently set to 64 elements. It allows to keep all operands of vector operations in cache, even for complex expressions.

The `vops` extension implements special vector types to be used instead of scalar types for table columns. The available types are listed in [Section F.76.6.1](#). To use `vops`, you have to create vectorized projections of original tables, with at least some attributes using these tile types, as explained in [Section F.76.5.1](#).

The original table can be treated as a write-optimized storage: if it has no indexes, Postgres Pro can provide a very fast insertion speed, comparable to raw disk write speed. Vectorized projection can be treated as a read-optimized storage, which is most efficient for running OLAP queries.

Once all the data is in the tile-based format, you can run vectorized queries on this data. `vops` provides a set of [vector operators](#) to work with vector types. Using these operators, you can write queries for filtering and aggregation, similar to SQL queries. For details, see [Section F.76.5.2](#).

For other query types, `vops` allows to work with vectorized data via `postgres_fdw`. You can add vectorized data to your database cluster as a foreign table and use regular SQL for running any types of queries on this data. Using the implicit type casts and post-parse `ANALYZE` hook, the `vops` extension either transforms the query to use vector operators for filtering and aggregation, or processes the data using scalar operators for other query types. For details, see [Section F.76.5.3](#).

## F.76.5. Usage

### F.76.5.1. Converting Data into Vectorized Format

To start using vector operations, you have to convert your data into a vectorized format, as explained below.

#### 1. Create an empty vectorized table.

To use vector operations, you need to load data into a tile-based vectorized table, which can be treated as a *projection* of the original table. It can map all columns of the original table, or include some of the most frequently used columns only. To create a vectorized table, you can use the regular [CREATE TABLE](#) syntax, but at least some of the columns must be of [vector types](#).

For example, suppose you have the following table from the TPC-H benchmark:

```
CREATE TABLE lineitem(  
    l_orderkey integer,  
    l_partkey integer,  
    l_suppkey integer,  
    l_linenummer integer,  
    l_quantity double precision,  
    l_extendedprice double precision,  
    l_discount double precision,  
    l_tax double precision,  
    l_returnflag "char",
```

```
l_linestatus "char",
l_shipdate date,
l_commitdate date,
l_receiptdate date,
l_shipinstruct char(25),
l_shipmode char(10),
l_comment char(44));
```

To create a vectorized projection that includes only a subset of the original columns, you can run:

```
CREATE TABLE vops_lineitem(
  l_shipdate vops_date not null,
  l_quantity vops_float8 not null,
  l_extendedprice vops_float8 not null,
  l_discount vops_float8 not null,
  l_tax vops_float8 not null,
  l_returnflag vops_char not null,
  l_linestatus vops_char not null
);
```

Alternatively, you can keep the scalar type for some of the columns. In this case, you can sort the data by these columns when loading the data. For example, let's create another vectorized projection where `l_returnflag` and `l_linestatus` fields remain scalar:

```
CREATE TABLE vops_lineitem_projection(
  l_shipdate vops_date not null,
  l_quantity vops_float8 not null,
  l_extendedprice vops_float8 not null,
  l_discount vops_float8 not null,
  l_tax vops_float8 not null,
  l_returnflag "char" not null,
  l_linestatus "char" not null
);
```

In this table, `l_returnflag` and `l_linestatus` fields are scalar, while all the other fields are of the vector types that can be used in vector operations.

## 2. Load the data into the vectorized table.

- If the data to load is already stored in your database, use the [populate\(\)](#) function to preprocess the data and unite attribute values of several rows inside a single tile. This function loads the data from the original table into its vectorized projection, using vector types instead of scalar types, as specified in the created empty table.

For example:

```
SELECT populate(destination := 'vops_lineitem'::regclass, source :=
  'lineitem'::regclass);
```

Once the table is populated, you can start running queries performing sequential scan.

Optionally, you can sort the data by one or more scalar columns when loading the data:

```
SELECT populate(destination := 'vops_lineitem_projection'::regclass, source :=
  'lineitem'::regclass, sort := 'l_returnflag,l_linestatus');
```

If you sort the original table by the scalar columns that have a lot of duplicates, `vops` can effectively collapse them and store the corresponding attribute values in tiles, which can reduce the occupied space, speed up queries, and facilitate [index creation](#) on these scalar columns.

- If your data is not yet loaded into the database and you would like to avoid having two copies of the same dataset, you can import the data into a vectorized table directly from a CSV file using the [import\(\)](#) function, bypassing creation of a regular table. For example:

```
SELECT import(destination := 'vops_lineitem'::regclass, csv_path := '/mnt/data/lineitem.csv', separator := '|');
```

For detailed description and syntax of the `populate()` and `import()` functions, see [Section F.76.6.4](#).

Once your data is in the tile-based format, you can run queries on this data using [vector operators](#), as described in [Section F.76.5.2](#). If you create a foreign vectorized table, you can also run regular SQL queries. See [Section F.76.5.3](#) for details.

## F.76.5.2. Running Queries on Vectorized Data

`vops` implements its own vector functions and operators for working with vectorized data. See [Section F.76.6](#) for the full list of vector functions and operators and their usage specifics.

### F.76.5.2.1. Aggregating Vectorized Data

OLAP queries often aggregate large volumes of data. To enable aggregate operations for vector types, `vops` implements the following aggregate functions for vectorized data: `count`, `min`, `max`, `avg`, `var_pop`, `var_samp`, `variance`, `stddev_pop`, `stddev_samp`, `stddev`. Besides, `vops` provides the `wavg` aggregate function that calculates volume-weighted average price (VWAP).

The `vops` extension supports the following types of aggregates:

- grand aggregates calculated for the whole table
- aggregates for subsets of table rows defined by the `GROUP BY` clause

#### F.76.5.2.1.1. Calculating Grand Aggregates

To calculate grand aggregates, you can use the provided vector aggregate functions exactly like in regular SQL queries.

##### Examples:

To calculate volume-weighted average price, run the following query:

```
SELECT wavg(l_extendedprice, l_quantity) FROM vops_lineitem;
```

To calculate the company revenue for the year 1996 based on discounted prices of the shipped goods, run:

```
SELECT sum(l_extendedprice*l_discount) AS revenue
FROM vops_lineitem
WHERE filter(betwixt(l_shipdate, '1996-01-01', '1997-01-01')
& betwixt(l_discount, 0.08, 0.1)
& (l_quantity < 24));
```

#### F.76.5.2.1.2. Calculating Grouped Aggregates

To support grouped aggregates, `vops` provides `map()` and `reduce()` functions:

- The `map()` function collects aggregate states for all groups in a hash table. Its syntax is as follows:

```
map(group_by_expression,
    aggregate_list, expr {,
    expr })
```

- The `reduce()` function iterates through the hash table constructed by `map` and returns the set. The `reduce` function is needed because the result of aggregation in Postgres Pro cannot be a set.

Consider the following example:

```
SELECT reduce(map(l_returnflag||l_linestatus, 'sum,sum,sum,sum,avg,avg,avg',
    l_quantity,
    l_extendedprice,
    l_extendedprice*(1-l_discount),
```

```
l_extendedprice*(1-l_discount)*(1+l_tax),
l_quantity,
l_extendedprice,
l_discount))
FROM vops_lineitem
WHERE filter(l_shipdate <= '1998-12-01'::date);
```

The concatenation operator `||` performs grouping by two columns. The `vops` extension supports grouping only by an integer type. The `map` function accepts aggregation arguments as a variadic array, so all elements of this array should have the same type. For example, you cannot calculate aggregates for `vops_float4` and `vops_int8` columns in a single operation.

An aggregate string in `map` function should contain the list of aggregate functions to call, in a comma-separated format. Standard lowercase names should be used: `count`, `sum`, `agg`, `min`, `max`. Count is executed for the particular column: `count(x)`. There is no need to explicitly specify `count(*)` because the number of records in each group is returned by `reduce` function in any case.

`reduce` function returns set of the `vops_aggregate` type. It contains three components: the value of the `GROUP BY` expression, the number of records in the group, and an array of floats with aggregate values. The values of all aggregates, including `count` and `min/max`, are returned as floats.

Alternatively, you can partition the vectorized table by the `GROUP BY` fields to calculate grouped aggregates. In this case, grouping keys are stored as regular scalar values, while other fields are stored inside tiles. Now Postgres Pro executor will execute `vops` aggregates for each group:

```
SELECT
    l_returnflag,
    l_linestatus,
    sum(l_quantity) as sum_qty,
    sum(l_extendedprice) AS sum_base_price,
    sum(l_extendedprice*(1-l_discount)) AS sum_disc_price,
    sum(l_extendedprice*(1-l_discount)*(1+l_tax)) AS sum_charge,
    avg(l_quantity) AS avg_qty,
    avg(l_extendedprice) AS avg_price,
    avg(l_discount) AS avg_disc,
    count(*) AS count_order
FROM
    vops_lineitem_projection
WHERE
    filter(l_shipdate <= '1998-12-01'::date)
GROUP BY
    l_returnflag,
    l_linestatus
ORDER BY
    l_returnflag,
    l_linestatus;
```

In this example, `l_returnflag` and `l_linestatus` fields of the `vops_lineitem_projection` table have the `char` type, while all the other used fields are of vector types. The query above is executed even faster than query with the `map()` and `reduce()` functions. The main problem with this approach is that you have to create a separate projection for each combination of the `GROUP BY` keys to be used in queries.

#### F.76.5.2.2. Using Vector Window Functions

The `vops` extension provides limited support for Postgres Pro window functions. It provides `mcount`, `msum`, `mmin`, `mmax`, `mavg`, and `lag` functions that correspond to the standard Postgres Pro window functions `count`, `sum`, `min`, `max`, `avg`, and `lag` functions, respectively.

Note the following important restrictions:

1. Filtering, grouping, and sorting can be done only by scalar attributes.

2. Vector window functions only support window frames specified with `ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW`.

### Examples:

```
SELECT vops_unnest(t.*)
FROM (SELECT mcount(*) over w,mcount(x) over w,msum(x) over w,mavg(x) over w,mmin(x)
over w,mmax(x) over w,x - lag(x) over w
FROM v window w
AS (rows between unbounded preceding and current row)) t;
```

#### F.76.5.2.3. Converting Results to Horizontal Format

A query from the `vops` projection returns a set of tiles. The output function of a tile type can print the tile contents. However, if you want to convert the result to the horizontal format where each tuple represents a single record, use the `vops-unnest` function. For example:

```
SELECT vops_unnest(l.*)
FROM vops_lineitem l
WHERE filter(l_shipdate >= '1998-12-01'::date);
```

#### F.76.5.3. Using Standard SQL for Vector Operations

Vector operators can efficiently execute only filtering and aggregation queries. For other query types, you have to run regular SQL queries. The `vops` extension offers the following options:

- Use the original table, if any.
- Enable a foreign data wrapper (FDW) using `postgres_fdw` to present a vectorized table to Postgres Pro as a regular table with scalar column types.

If you use `postgres_fdw` with the `vops` extension, vectorized data is not really foreign: it is stored inside the database in an alternative vectorized format. FDW allows to hide specifics of the vectorized format and provides the following opportunities for working with vectorized data:

1. Extract the data from a vectorized table and present it in the horizontal format, so that it can be processed by upper nodes in the query execution plan.
2. Push filtering and aggregation queries down to vector operations.
3. Get statistic for the underlying table by running `ANALYZE` for the foreign table. The collected statistic can be used by the query optimizer, so query execution plan should be almost the same as for regular tables.

Thus, by placing a vectorized projection under FDW, you can use standard SQL without any `vops`-specific functions to perform sequential scan and aggregation queries as if they are explicitly written for the `vops` table, and execute any other queries on this data at the same time, including `JOIN` operations, common table expressions (CTE), etc. The queries that can be efficiently executed by vector operations will be pushed by Postgres Pro query optimizer to `vops` FDW and will be executed using vector operators. For other queries, the data is fetched from vectorized tables as standard tuples. If it is determined that vector operations are required, `vops` uses a post-parse `ANALYZE` hook that replaces scalar boolean operations with vector boolean operations:

| Original Expression                    | Transformed Expression                     |
|----------------------------------------|--------------------------------------------|
| <code>NOT filter(o1)</code>            | <code>filter(vops_bool_not(o1))</code>     |
| <code>filter(o1) AND filter(o2)</code> | <code>filter(vops_bool_and(o1, o2))</code> |
| <code>filter(o1) OR filter(o2)</code>  | <code>filter(vops_bool_or(o1, o2))</code>  |

There is only one difference between standard SQL and its vectorized extension. You still have to perform explicit type cast for string literals. For example, `l_shipdate <= '1998-12-01'` will not work for the `l_shipdate` column with vector type. Postgres Pro Enterprise has two overloaded versions of the `<=` operator to choose the appropriate scalar or vector type:

- `vops_date <= vops_date`

- vops\_date <= date

The example below shows creation of a vectorized table via `postgres_fdw` and some queries on it:

```
CREATE FOREIGN TABLE lineitem_fdw (  
    l_suppkey int4 not null,  
    l_orderkey int4 not null,  
    l_partkey int4 not null,  
    l_shipdate date not null,  
    l_quantity float8 not null,  
    l_extendedprice float8 not null,  
    l_discount float8 not null,  
    l_tax float8 not null,  
    l_returnflag "char" not null,  
    l_linestatus "char" not null  
) SERVER vops_server OPTIONS (table_name 'vops_lineitem');
```

```
EXPLAIN SELECT  
    sum(l_extendedprice*l_discount) AS revenue  
FROM  
    lineitem_fdw  
WHERE  
    l_shipdate BETWEEN '1996-01-01' AND '1997-01-01'  
    AND l_discount BETWEEN 0.08 AND 0.1  
    AND l_quantity < 24;
```

QUERY PLAN

```
-----  
Foreign Scan  (cost=1903.26..1664020.23 rows=1 width=4)  
(1 row)
```

-- Filter was pushed down to FDW

```
EXPLAIN SELECT  
    n_name,  
    count(*),  
    sum(l_extendedprice * (1-l_discount)) AS revenue  
FROM  
    customer_fdw JOIN orders_fdw ON c_custkey = o_custkey  
    JOIN lineitem_fdw ON l_orderkey = o_orderkey  
    JOIN supplier_fdw ON l_suppkey = s_suppkey  
    JOIN nation ON c_nationkey = n_nationkey  
    JOIN region ON n_regionkey = r_regionkey  
WHERE  
    c_nationkey = s_nationkey  
    AND r_name = 'ASIA'  
    AND o_orderdate >= '1996-01-01'  
    AND o_orderdate < '1997-01-01'  
GROUP BY  
    n_name  
ORDER BY  
    revenue desc;

                                        Filter:
((r_name)::text = 'ASIA'::text)
                                        -> Hash (cost=294718.76..294718.76 rows=2284376 width=8)
                                            -> Foreign Scan on orders_fdw (cost=0.00..294718.76
rows=2284376 width=8)
                                            -> Hash (cost=32605.64..32605.64 rows=1500032 width=8)
                                                -> Foreign Scan on customer_fdw (cost=0.00..32605.64
rows=1500032 width=8)

-- filter on orders range is pushed to FDW

```

### F.76.5.4. Building Indexes for Vectorized Tables

Analytic queries are usually performed on the data for which no indexes are defined. Vector operations on tiles are most effective in this case. However, you can still use indexes with vectorized data.

Since each tile represents multiple values, an index can be used only for some preliminary, non-precise filtering of data. The `vops` extension provides the following pairs of functions to obtain boundary values stored in the tile:

- `first()` and `last()` functions should be used for sorted dataset. In this case, the first and the last values in the tile are the smallest and the largest values in the tile, respectively.
- `high()` and `low()` functions should be used for unsorted data. These functions are more expensive because they need to inspect all tile values.

Using the returned values, you can construct functional indexes for vectorized data. The BRIN index seems to be the best choice:

```
CREATE INDEX low_boundary ON trades
USING brin(first(day)); -- trades table is ordered by day
CREATE INDEX high_boundary ON trades
USING brin(last(day)); -- trades table is ordered by day
```

Now you can use the created indexes in queries. However, you have to recheck the precise condition because such an index only gives an approximate result:

```
SELECT sum(price) FROM trades
WHERE first(day) >= '2015-01-01' AND last(day) <= '2016-01-01'
AND filter(betwixt(day, '2015-01-01', '2016-01-01'));
```

### F.76.5.5. Automating Projection Usage

`vops` can automate most of the operations required to create and maintain vectorized data projections. In this case, you do not have to use [postgres\\_fdw](#): `vops` can redirect regular SQL queries to projection tables automatically. However, these queries must satisfy the following criteria to get redirected:

- The query does not contain joins.
- The query performs aggregation of vector columns.
- All other expressions in the target list, as well as `ORDER BY` and `GROUP BY` clauses refer only to scalar columns.

To enable automatic query redirection to a vectorized projection of your data, do the following:

#### 1. Create a vectorized projection of the table using the [create\\_projection\(\)](#) function.

For example, to create a projection for the `lineitem` table shown above, similar to the `vops_lineitem`, run:

```
SELECT create_projection('auto_vops_lineitem', 'lineitem',
    array['l_shipdate', 'l_quantity', 'l_extendedprice', 'l_discount', 'l_tax'],
    array['l_returnflag', 'l_linestatus']);
```

In this example, the first two arguments specify the projection table and the original table, respectively, the first array defines all the vector columns to be included into the projection, and the second array specifies the scalar columns that will be used for grouping vectorized data into tiles.

Additionally, you can provide an optional `order_by` parameter to speed up subsequent projection refresh operations. The `order_by` values should be unique. For example, to sort all table entries by `l_shipdate`, you can create a projection table as follows:

```
SELECT create_projection('auto_vops_lineitem_ordered', 'lineitem',
    array['l_shipdate', 'l_quantity', 'l_extendedprice', 'l_discount', 'l_tax'],
    array['l_returnflag', 'l_linestatus'],
    'l_shipdate');
```

#### 2. Set the [vops.auto\\_substitute\\_projections](#) parameter to `on`.

Now all queries that `vops` can redirect to the `auto_vops_lineitem` projection table will be run on the vectorized data.

Projections are not updated automatically, so once the original table gets updated, implicitly redirected queries can start returning inaccurate results. To avoid this, you have to refresh the projections before running queries on the vectorized data. For this purpose, `vops` provides the `pname_refresh()` functions, where the `pname` prefix is the name of the projection you need to refresh. For example, to refresh the `auto_vops_lineitem` projection, run:

```
SELECT auto_vops_lineitem_refresh();
```

This function calls the `populate()` method to update all the fields present in the projection. If you have specified the optional `order_by` parameter when creating the projection, only the new data will be im-

ported from the original table, selecting only the rows with the `order_by` column value greater than the maximal value of this column in the projection. Otherwise, the whole table will be re-written. The `populate()` method also takes the grouping columns into account to efficiently group the imported data in tiles.

If you have specified the `order_by` attribute when creating a projection, `vops` also creates the following indexes:

- Two functional BRIN indexes on `first()` and `last()` functions of this attribute. Such indexes allow to efficiently select time slices. For example, if the original query contains predicates like `(l_shipdate between '01-01-2017' and '01-01-2018')`, `vops` adds the `(first(l_shipdate) >= '01-01-2017' and last(l_shipdate) >= '01-01-2018')` conjuncts when redirecting the query, so that Postgres Pro optimizer can quickly locate the affected pages using BRIN indexes.
- A BRIN index for scalar columns used for grouping. Such index allows to efficiently select groups and perform index joins.

## F.76.6. Reference

### F.76.6.1. Vector Types

The `vops` extension supports all basic Postgres Pro numeric types: 1-, 2-, 4-, 8-byte integers, as well as 4- and 8-byte floats. The `date` and `timestamp` types are using the same implementation as `int4` and `int8`, respectively. The table below illustrates the available vector types, as compared to the corresponding SQL and C types.

| SQL Type                              | C Type    | vops Vector Type      |
|---------------------------------------|-----------|-----------------------|
| bool                                  | bool      | vops_bool             |
| "char"                                | char      | vops_char             |
| date                                  | DateADT   | vops_date             |
| int2                                  | int16     | vops_int2             |
| int4                                  | int32     | vops_int4             |
| int8                                  | int64     | vops_int8             |
| float4                                | float4    | vops_float4           |
| float8                                | float8    | vops_float8           |
| timestamp                             | Timestamp | vops_timestamp        |
| char( <i>N</i> ), varchar( <i>N</i> ) | text      | vops_text( <i>N</i> ) |

#### Note

For performance reasons, using `vops_text` for single-character strings is not recommended. If you are using strings as identifiers, you can place them in a dictionary and use integer identifiers instead of the original strings.

### F.76.6.2. Vector Operators

The `vops` extension provides a set of operators for vector types.

#### F.76.6.2.1. Mathematical Operators

For mathematical operations, `vops` overloads regular SQL operators, so they can take operands of both vector and scalar types.

| Operator | Description |
|----------|-------------|
| +        | Addition    |

| Operator | Description                                                                                                                                                                                                                                                           |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| –        | Binary subtraction or unary negation                                                                                                                                                                                                                                  |
| *        | Multiplication                                                                                                                                                                                                                                                        |
| /        | Division                                                                                                                                                                                                                                                              |
|          | Concatenation. This operator is only supported for <code>char</code> , <code>int2</code> , and <code>int4</code> types. It returns an integer type of a doubled size:<br><br><pre>(char    char) -&gt; int2 (int2    int2) -&gt; int4 (int4    int4) -&gt; int8</pre> |

#### F.76.6.2.2. Comparison Operators

For comparison operations, `vops` overloads regular SQL operators, so they can take operands of both vector and scalar types.

| Operator | Description            |
|----------|------------------------|
| =        | Equals                 |
| <>       | Not equals             |
| <        | Less than              |
| <=       | Less than or equals    |
| >        | Greater than           |
| >=       | Greater than or equals |

#### F.76.6.2.3. Boolean Operators

Boolean operators `AND`, `OR`, and `NOT` cannot be overloaded, so `vops` provides its own implementation of boolean operators for vector types:

| Operator | Description |
|----------|-------------|
| &        | Boolean AND |
|          | Boolean OR  |
| !        | Boolean NOT |

Vector boolean operators have the following usage specifics:

- The precedence of vector boolean operators is different from `AND`, `OR`, and `NOT`, so you have to enclose the operands into parentheses. For example:  

```
(x=1) | (x=2)
```
- The result of vector boolean operations is `vops_bool`. Since Postgres Pro requires predicate expressions to have a regular boolean type, you have to convert the result to the `bool` type using the `filter()` function. Taking a vector boolean expression, this function calculates a `filter_mask` value that defines the result of this boolean operation for each vector element. If all mask bits are zero (the predicate is false for all vector elements), then `filter()` returns `false`, and Postgres Pro executor skips this record. Otherwise, `true` is returned, so vector operators will check the `filter_mask` value for the selected vector elements in subsequent operations.
- When using vector boolean operators, you have to use explicit cast of string constants to the required data type.

#### F.76.6.3. Comparison Functions

| Function                           | Description                                                |
|------------------------------------|------------------------------------------------------------|
| <code>bitwixt(x, low, high)</code> | Same as the <code>x BETWEEN low AND high</code> predicate. |

| Function                      | Description                                          |
|-------------------------------|------------------------------------------------------|
| <code>is_null(x)</code>       | Same as the <i>expression</i> IS NULL predicate.     |
| <code>is_not_null(x)</code>   | Same as the <i>expression</i> IS NOT NULL predicate. |
| <code>ifnull(x, subst)</code> | Same as the COALESCE function.                       |

#### F.76.6.4. Conversion Functions

```
create_projection(projection_name text, source_table regclass, vector_columns text[],
scalar_columns text[] DEFAULT null, order_by text DEFAULT null)
```

Creates a projection table with specified name and attributes and updates the `vops_projections` table to include the information about this projection, so that the optimizer can automatically redirect queries from the original table to its projection. It also creates the [pname\\_refresh\(\)](#) function that can update the projection.

Arguments:

- *projection\_name* — the name of the projection table.
- *source\_table* — the original Postgres Pro table for which to create a vectorized projection.
- *vector\_columns* — an array of column names that will be stored as `vops` tiles.
- *scalar\_columns* — an array of column names that will preserve its original scalar type. These columns will be used to group table rows into `vops` tiles. `vops` automatically builds a BRIN index over such columns.
- *order\_by* — an optional vector column that can be used to sort data in the projection table. Sorting can be useful to incrementally update the projection after the original table updates using the [pname\\_refresh\(\)](#) function. This column should contain unique timestamp values, such as trade dates. `vops` automatically builds a functional BRIN index for `first()` and `last()` functions of this column.

Examples:

```
SELECT
  create_projection('vops_lineitem', 'lineitem', array['l_shipdate', 'l_quantity', 'l_extended
pname_refresh()
```

Refreshes the *pname* projection table.

Examples:

Refresh the `vops_lineitem` projection:

```
SELECT vops_lineitem_refresh();
drop_projection(projection_name text)
```

Drops the specified projection and the corresponding refresh function, as well as removes the information about this projection from the `vops_projections` table.

Examples:

Drop the `vops_lineitem` projection:

```
SELECT drop_projection(vops_lineitem);
populate(destination regclass, source regclass, predicate cstring DEFAULT null, sort
cstring DEFAULT null)
```

Copies the data from an existing table to its vectorized projection and returns the number of imported rows (`bigint`).

**Arguments:**

- *destination* — target table to copy the data into.

Type: regclass

- *source* — source table to copy the data from.

Type: regclass

- *predicate* — restricts the amount of imported data (optional). Using this argument, you can upload only the most recent records.

Type: cstring

- *sort* — sorts the source data to define the order in which the data needs to be loaded (optional).

Type: cstring

**Examples:**

```
SELECT populate(destination := 'vops_lineitem'::regclass, source :=  
  'lineitem'::regclass);
```

```
SELECT populate(destination := 'vops_lineitem_projection'::regclass, source :=  
  'lineitem_projection'::regclass, sort := 'l_returnflag,l_linestatus');
```

```
import(destination regclass, csv_path cstring, separator cstring DEFAULT ',', skip integer  
DEFAULT 0)
```

Loads the data into a `vops` table directly from a CSV file, bypassing creation of a regular table, and returns the number of imported rows (`bigint`). Use this function to avoid storing two copies of the same dataset.

**Arguments:**

- *destination* — target table to copy the data into.

Type: regclass

- *csv\_path* — the path to the CSV file to copy the data from.

Type: cstring

- *separator* — specifies the field separator used in the CSV file (optional). By default, the comma is assumed to be the field separator.

Type: cstring

- *skip* — specifies the number of rows in the CSV header that do not need to be imported (optional).

Default: 0

Type: cstring

**Examples:**

```
SELECT import(destination := 'vops_lineitem'::regclass, csv_path := '/mnt/data/  
lineitem.csv', separator := '|');
```

```
vops_unnest(anyelement)
```

Scatters records with `vops` types into records with scalar types.

## F.76.6.5. Configuration Parameters

`vops.auto_substitute_projections` (boolean)

Enables automatic query redirection to projection tables. For correct results, you have to ensure that the projection is synchronized with the original table.

Default: `off`

## F.76.7. Authors

Postgres Professional, Moscow, Russia

## F.77. xml2

The `xml2` module provides XPath querying and XSLT functionality.

### F.77.1. Deprecation Notice

From PostgreSQL 8.3 on, there is XML-related functionality based on the SQL/XML standard in the core server. That functionality covers XML syntax checking and XPath queries, which is what this module does, and more, but the API is not at all compatible. It is planned that this module will be removed in a future version of Postgres Pro in favor of the newer standard API, so you are encouraged to try converting your applications. If you find that some of the functionality of this module is not available in an adequate form with the newer API, please explain your issue to [pgsql-hackers@lists.postgresql.org](mailto:pgsql-hackers@lists.postgresql.org) so that the deficiency can be addressed.

### F.77.2. Description of Functions

[Table F.56](#) shows the functions provided by this module. These functions provide straightforward XML parsing and XPath queries.

**Table F.56. `xml2` Functions**

| Function                                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>xml_valid ( document text ) → boolean</code>                                         | Parses the given document and returns true if the document is well-formed XML. (Note: this is an alias for the standard Postgres Pro function <code>xml_is_well_formed()</code> . The name <code>xml_valid()</code> is technically incorrect since validity and well-formedness have different meanings in XML.)                                                                                                                                                  |
| <code>xpath_string ( document text, query text ) → text</code>                             | Evaluates the XPath query on the supplied document, and casts the result to <code>text</code> .                                                                                                                                                                                                                                                                                                                                                                   |
| <code>xpath_number ( document text, query text ) → real</code>                             | Evaluates the XPath query on the supplied document, and casts the result to <code>real</code> .                                                                                                                                                                                                                                                                                                                                                                   |
| <code>xpath_bool ( document text, query text ) → boolean</code>                            | Evaluates the XPath query on the supplied document, and casts the result to <code>boolean</code> .                                                                                                                                                                                                                                                                                                                                                                |
| <code>xpath_nodeset ( document text, query text, toptag text, itemtag text ) → text</code> | Evaluates the query on the document and wraps the result in XML tags. If the result is multi-valued, the output will look like:<br><br><code>&lt;toptag&gt;</code><br><code>&lt;itemtag&gt;Value 1 which could be an XML fragment&lt;/itemtag&gt;</code><br><code>&lt;itemtag&gt;Value 2....&lt;/itemtag&gt;</code><br><code>&lt;/toptag&gt;</code><br><br>If either <code>toptag</code> or <code>itemtag</code> is an empty string, the relevant tag is omitted. |

| Function                                                                                                                                                                                                                                                                  | Description |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| <code>xpath_node</code> ( <i>document</i> text, <i>query</i> text, <i>itemtag</i> text ) → text<br>Like <code>xpath_node</code> (document, query, toptag, itemtag) but result omits <i>toptag</i> .                                                                       |             |
| <code>xpath_node</code> ( <i>document</i> text, <i>query</i> text ) → text<br>Like <code>xpath_node</code> (document, query, toptag, itemtag) but result omits both tags.                                                                                                 |             |
| <code>xpath_list</code> ( <i>document</i> text, <i>query</i> text, <i>separator</i> text ) → text<br>Evaluates the query on the document and returns multiple values separated by the specified separator, for example Value 1,Value 2,Value 3 if <i>separator</i> is , . |             |
| <code>xpath_list</code> ( <i>document</i> text, <i>query</i> text ) → text<br>This is a wrapper for the above function that uses , as the separator.                                                                                                                      |             |

### F.77.3. xpath\_table

`xpath_table`(text key, text document, text relation, text xpaths, text criteria) returns setof record

`xpath_table` is a table function that evaluates a set of XPath queries on each of a set of documents and returns the results as a table. The primary key field from the original document table is returned as the first column of the result so that the result set can readily be used in joins. The parameters are described in [Table F.57](#).

**Table F.57. xpath\_table Parameters**

| Parameter       | Description                                                                                                                                                                                                  |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>key</i>      | the name of the “key” field — this is just a field to be used as the first column of the output table, i.e., it identifies the record from which each output row came (see note below about multiple values) |
| <i>document</i> | the name of the field containing the XML document                                                                                                                                                            |
| <i>relation</i> | the name of the table or view containing the documents                                                                                                                                                       |
| <i>xpaths</i>   | one or more XPath expressions, separated by                                                                                                                                                                  |
| <i>criteria</i> | the contents of the WHERE clause. This cannot be omitted, so use true or 1=1 if you want to process all the rows in the relation                                                                             |

These parameters (except the XPath strings) are just substituted into a plain SQL SELECT statement, so you have some flexibility — the statement is

```
SELECT <key>, <document> FROM <relation> WHERE <criteria>
```

so those parameters can be *anything* valid in those particular locations. The result from this SELECT needs to return exactly two columns (which it will unless you try to list multiple fields for key or document). Beware that this simplistic approach requires that you validate any user-supplied values to avoid SQL injection attacks.

The function has to be used in a FROM expression, with an AS clause to specify the output columns; for example

```
SELECT * FROM
xpath_table('article_id',
            'article_xml',
            'articles',
            '/article/author|/article/pages|/article/title',
            'date_entered > ''2003-01-01'' ')
AS t(article_id integer, author text, page_count integer, title text);
```

The `AS` clause defines the names and types of the columns in the output table. The first is the “key” field and the rest correspond to the XPath queries. If there are more XPath queries than result columns, the extra queries will be ignored. If there are more result columns than XPath queries, the extra columns will be `NULL`.

Notice that this example defines the `page_count` result column as an integer. The function deals internally with string representations, so when you say you want an integer in the output, it will take the string representation of the XPath result and use Postgres Pro input functions to transform it into an integer (or whatever type the `AS` clause requests). An error will result if it can't do this — for example if the result is empty — so you may wish to just stick to `text` as the column type if you think your data has any problems.

The calling `SELECT` statement doesn't necessarily have to be just `SELECT *` — it can reference the output columns by name or join them to other tables. The function produces a virtual table with which you can perform any operation you wish (e.g., aggregation, joining, sorting etc). So we could also have:

```
SELECT t.title, p.fullname, p.email
FROM xpath_table('article_id', 'article_xml', 'articles',
                '/article/title|article/author/@id',
                'xpath_string(article_xml, '/article/@date') > ''2003-03-20'' ')
     AS t(article_id integer, title text, author_id integer),
     tblPeopleInfo AS p
WHERE t.author_id = p.person_id;
```

as a more complicated example. Of course, you could wrap all of this in a view for convenience.

### F.77.3.1. Multivalued Results

The `xpath_table` function assumes that the results of each XPath query might be multivalued, so the number of rows returned by the function may not be the same as the number of input documents. The first row returned contains the first result from each query, the second row the second result from each query. If one of the queries has fewer values than the others, null values will be returned instead.

In some cases, a user will know that a given XPath query will return only a single result (perhaps a unique document identifier) — if used alongside an XPath query returning multiple results, the single-valued result will appear only on the first row of the result. The solution to this is to use the key field as part of a join against a simpler XPath query. As an example:

```
CREATE TABLE test (
    id int PRIMARY KEY,
    xml text
);

INSERT INTO test VALUES (1, '<doc num="C1">
<line num="L1"><a>1</a><b>2</b><c>3</c></line>
<line num="L2"><a>11</a><b>22</b><c>33</c></line>
</doc>');

INSERT INTO test VALUES (2, '<doc num="C2">
<line num="L1"><a>111</a><b>222</b><c>333</c></line>
<line num="L2"><a>111</a><b>222</b><c>333</c></line>
</doc>');

SELECT * FROM
    xpath_table('id','xml','test',
                '/doc/@num|doc/line/@num|doc/line/a|doc/line/b|doc/line/c',
                'true')
     AS t(id int, doc_num varchar(10), line_num varchar(10), val1 int, val2 int, val3 int)
WHERE id = 1 ORDER BY doc_num, line_num
```

Additional Supplied Modules  
and Extensions Shipped in  
postgrespro-ent-14-contrib

| id | doc_num | line_num | val1 | val2 | val3 |
|----|---------|----------|------|------|------|
| 1  | C1      | L1       | 1    | 2    | 3    |
| 1  |         | L2       | 11   | 22   | 33   |

To get `doc_num` on every line, the solution is to use two invocations of `xpath_table` and join the results:

```
SELECT t.*,i.doc_num FROM
  xpath_table('id', 'xml', 'test',
    '/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
    'true')
  AS t(id int, line_num varchar(10), val1 int, val2 int, val3 int),
  xpath_table('id', 'xml', 'test', '/doc/@num', 'true')
  AS i(id int, doc_num varchar(10))
WHERE i.id=t.id AND i.id=1
ORDER BY doc_num, line_num;
```

| id | line_num | val1 | val2 | val3 | doc_num |
|----|----------|------|------|------|---------|
| 1  | L1       | 1    | 2    | 3    | C1      |
| 1  | L2       | 11   | 22   | 33   | C1      |

(2 rows)

## F.77.4. XSLT Functions

The following functions are available if `libxslt` is installed:

### F.77.4.1. `xslt_process`

`xslt_process(text document, text stylesheet, text paramlist)` returns text

This function applies the XSL stylesheet to the document and returns the transformed result. The `paramlist` is a list of parameter assignments to be used in the transformation, specified in the form `a=1,b=2`. Note that the parameter parsing is very simple-minded: parameter values cannot contain commas!

There is also a two-parameter version of `xslt_process` which does not pass any parameters to the transformation.

## F.77.5. Author

John Gray <jgray@azuli.co.uk>

Development of this module was sponsored by Torchbox Ltd. ([www.torchbox.com](http://www.torchbox.com)). It has the same BSD license as Postgres Pro.

# Appendix G. Postgres Pro Modules and Extensions Shipped as Individual Packages

This appendix contains Postgres Pro modules and extensions that are made available in Postgres Pro Enterprise as individual packages. These packages are listed in [Section 17.1.6.1](#), and the documentation for each module explains which package to choose to install it. [Appendix F](#) covers more modules and extensions included in the Postgres Pro Enterprise distribution. The `pg_portal_modify` extension is also shipped as an individual package (see [Section 17.1.6.1](#) for details).

## G.1. pgpro\_datactl — manage Postgres Pro Enterprise data files

### G.1.1. Overview

The `pgpro_datactl` utility provides tools for managing Postgres Pro Enterprise data files, including a module for CFS (Compressed File Storage) operations. This module offers the following functionalities:

- Retrieving metadata from compressed files, including their compression algorithm and location.
- Unpacking CFS files for further analysis.
- Repacking compressed files and changing their compression level.
- Preventing potential failures caused by corrupted files.

### G.1.2. Installation

`pgpro_datactl` is provided with Postgres Pro Enterprise as a separate pre-built package `pgpro-datactl-ent-14` (for the detailed installation instructions, see [Chapter 17](#)).

### G.1.3. Commands

`pgpro_datactl` supports the following commands:

- `unpack`
- `probe`
- `info`
- `repack`
- `ground`
- `stat`

#### G.1.3.1. Important Notes

Before running these commands, pay attention to the following operation specifics:

- The `repack` and `unpack` operations require the Postgres Pro Enterprise cluster to be *stopped*. This is necessary to prevent data corruption and ensure file consistency.
- When using the `--in-place` option with the `repack` command, note that:
  - The tablespace will be overwritten directly during the operation.
  - All the existing data in the target tablespace will be replaced.

### G.1.3.2. unpack

```
pgpro_datactl unpack --source=source_path --target=target_path  
[--calg=compression_algorithm] [--zero-on-error] [--log-level=logging_level] [--help]
```

Unpacks CFS files.

```
-s=source_path  
--source=source_path
```

Specifies the path to a compressed file or directory.

#### Note

The path must be in the directory named `PG_version_date` that contains the `pg_compression` file.

```
-t=target_path  
--target=target_path
```

Specifies the path to a directory where the unpacked files will be placed.

If the source and target directories are the same, files are unpacked with a `.dec` extension.

```
-c=compression_algorithm  
--calg=compression_algorithm
```

Specifies the compression algorithm used. If omitted, the `unpack` command will take this value from the `pg_compression` file.

```
--zero-on-error
```

If this option is specified, any corrupted blocks are replaced with zeros, preventing the process termination or error messages.

```
--log-level=logging_level
```

Sets the logging level. Possible values: `debug`, `info`, `warning`, and `error`.

Example:

```
pgpro_datactl unpack -s /path/to/archive.cfs -t /path/to/destination -c zstd
```

In this example, `unpack` extracts `archive.cfs` compressed with the `zstd` algorithm into the directory `/path/to/destination`.

### G.1.3.3. probe

```
pgpro_datactl probe --source=source_path [--log-level=logging_level] [--help]
```

Analyzes the specified file and identifies the following:

- Compression type: `zlib` or `zstd` compression algorithm.
- Fragmentation level: Analyzes the corresponding `*.cfm` file (if available) and reports the percentage of unused storage space in the physical file.
- Whether the file belongs to CFS: Checks the presence of an associated `*.cfm` file, which indicates whether the file belongs to a CFS archive.

```
-s=source_path  
--source=source_path
```

Specifies the path to the required file.

`--log-level=logging_level`

Sets the logging level. Possible values: debug, info, warning, and error.

Example output:

```
Probing path: /data/sample.dat
Has cfm file: Yes
pg_compression: zstd
Actual compression: zstd
Fragmentation: 5%
```

In this example, the file is compressed with the `zstd` algorithm, is part of a CFS archive, and has a fragmentation level of five percent.

#### G.1.3.4. info

```
pgpro_datactl info --source=source_path [--log-level=logging_level] [--help]
```

Analyzes the file and displays the following information:

- The file physical size, virtual size, and utilized file space in bytes.
- Whether the garbage collector (GC) is active.
- Whether the `*.cfm` file is present and accessible.

```
-s=source_path
--source=source_path
```

Specifies the path to the required file.

`--log-level=logging_level`

Sets the logging level. Possible values: debug, info, warning, and error.

Example output:

```
Physical size: 10485760
Virtual size: 9437184
Used size: 7864320
GC active: Yes
```

#### G.1.3.5. repack

```
pgpro_datactl repack --source=source_path --t-calg=target_compression_algorithm --
target=target_path
[--calg=compression_algorithm] [--clevel=compression_level]
[--zero-on-error] [--log-level=logging_level] [--in-place] [--help]
```

Changes the compression algorithm and/or compression level of CFS files.

Returns the following information:

- Compression algorithm ID
- Compression level
- Copy status: 1 (complete) or 0 (incomplete)

If interrupted, the process can resume from the point of failure by re-executing the command with identical compression options (both `--t-calg` and `--calg` values), leveraging per-datafile `.status` files to maintain the operation state.

```
-s=source_path
--source=source_path
```

Specifies the path to a compressed file or directory.

## Note

The path must be in the directory named `PG_version_date` that contains the `pg_compression` file.

`--t-calg=target_compression_algorithm`

Specifies the target compression algorithm. If omitted, the files will be decompressed (unpacked).

`-t=target_path`

`--target=target_path`

Specifies the output location for recompressed files.

`-c=compression_algorithm`

`--calg=compression_algorithm`

Specifies the current compression algorithm. If omitted, the `repack` command will take this value from the `pg_compression` file.

`--log-level=logging_level`

Sets the logging level. Possible values: `debug`, `info`, `warning`, and `error`.

`--clevel=compression_level`

Specifies the compression level for the chosen target compression algorithm. The default value is 1.

`--zero-on-error`

If this option is specified, any corrupted blocks are replaced with zeros, preventing the process termination or error messages.

`--in-place`

If this option is specified while `target_path` is omitted, the recompressed files will be placed in the source directory.

## Warning

Using this option will remove all the source files from the source directory, thus should be considered carefully.

### G.1.3.6. ground

```
pgpro_datactl ground --source=source_path --block-num=block_number  
[--calg=compression_algorithm] [--log-level=logging_level] [--help]
```

Replaces the specified corrupted blocks, which may appear during decompression, with zeros.

`-s=source_path`

`--source=source_path`

Specifies the path to the required file.

`--block-num=block_number`

Specifies the number of the block that should be replaced.

`-c=compression_algorithm`

`--calg=compression_algorithm`

Specifies the current compression algorithm. If the value does not match the CFS tablespace compression algorithm, the operation will complete with an error.

`--log-level=logging_level`

Sets the logging level. Possible values: debug, info, warning, and error.

Example:

```
pgpro_datactl ground -s /path/to/archive.cfs --block-num 4 --calg pglz
```

In this example, `ground` replaces the block number 4 with a zero and uses the `pglz` algorithm to compress it.

### G.1.3.7. stat

```
pgpro_datactl stat --source=source_path --cfs  
[--log-level=logging_level] [--help]
```

Collects tablespace statistics and outputs the results as a CSV file.

This command does not modify any files (read-only operation). No locks are acquired.

`-s=source_path`

`--source=source_path`

Specifies the path to a compressed file or directory.

#### Note

The path must be in the directory named `PG_version_date` that contains the `pg_compression` file.

`--cfs`

Specifies the tablespace type.

#### Note

Currently only the CFS type support is implemented.

`--log-level=logging_level`

Sets the logging level. Possible values: debug, info, warning, and error.

## G.1.4. pgpro\_datactl Error Codes

Table G.1 displays the error code ranges defined in `pgpro_datactl`.

According to the SQL standard, the first two characters of an error code denote the class of errors, while the last three characters indicate a specific condition within that class.

**Table G.1. pgpro\_datactl Error Code Ranges**

| Error Code | Condition          |
|------------|--------------------|
| 00XXX      | Success            |
| 10XXX      | Warning            |
| 20XXX      | Command-line error |
| 30XXX      | Database error     |
| 40XXX      | Source data error  |
| 50XXX      | Target data error  |

| Error Code | Condition           |
|------------|---------------------|
| 60XXX      | Filesystem/IO error |
| 70XXX      | Runtime error       |

Table G.2 lists all specific error codes and the actions that should be taken if these errors occur.

pgpro\_datactl uses the `PRODCtl-XXXXX` format. Warnings return a nonzero exit code but allow the utility to progress. Errors stop the current operation.

**Table G.2. pgpro\_datactl Error Codes**

| Error Code     | Message                             | Cause                                                              | Action                                                             |
|----------------|-------------------------------------|--------------------------------------------------------------------|--------------------------------------------------------------------|
| PROD-CTL-00000 | Success                             | The operation completed successfully.                              | No action required.                                                |
| PROD-CTL-10001 | File not found.                     | An optional input path is missing.                                 | Check the path. If intentional, the warning can be ignored.        |
| PROD-CTL-10002 | Failed to read file.                | A partial read, permission error, or transient IO issue occurred.  | Retry the operation. Check user permissions and disk status.       |
| PROD-CTL-10003 | Invalid parameter.                  | A noncritical argument is out of range or malformed.               | Enter a valid value, or a default value will be used to proceed.   |
| PROD-CTL-10004 | Failed to allocate memory.          | The system was low on memory during a non-critical step.           | Reduce concurrency or data size.                                   |
| PROD-CTL-10005 | Failed to create working directory. | The current or working directory could not be established.         | Check the path, permissions, and available disk space.             |
| PROD-CTL-10006 | File contains invalid content.      | An optional file failed validation.                                | Replace or skip the file.                                          |
| PROD-CTL-10007 | Failed to remove file.              | The file is locked, or permission was denied.                      | Close any handles to the file and adjust permissions.              |
| PROD-CTL-10008 | Parameter required but not set.     | An optional subtask required a value but used the default instead. | Provide the missing option to avoid the fallback behavior.         |
| PROD-CTL-20001 | Required parameter is missing.      | A mandatory command-line option is absent.                         | Supply the required option and rerun the command.                  |
| PROD-CTL-20002 | Invalid parameter.                  | A command-line option has an invalid value.                        | Enter a valid value according to the documentation.                |
| PROD-CTL-30001 | Database connection failed.         | A network, authentication, or DSN error occurred.                  | Check authentication, network connectivity, and SSL configuration. |
| PROD-CTL-30002 | Database query failed.              | An SQL error, timeout, or permission issue occurred.               | Check the SQL and logs. Fix schema or permission issues.           |
| PROD-CTL-40001 | Failed to read source file.         | An IO error occurred on input.                                     | Make sure the path exists and the user has access to it. Retry.    |
| PROD-CTL-40002 | Source file not found.              | A required input file is missing.                                  | Provide the correct file or fix the path.                          |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Error Code     | Message                          | Cause                                                              | Action                                                                            |
|----------------|----------------------------------|--------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| PROD-CTL-40003 | Failed to construct source path. | The root path, environment variable, or template is invalid.       | Fix the configuration and path template.                                          |
| PROD-CTL-40004 | File contains invalid content.   | Required input failed validation, or a checksum mismatch occurred. | Replace the file or fix its format.                                               |
| PROD-CTL-50001 | Target file write failed.        | A permission, disk quota, or disk error occurred.                  | Free up disk space, fix permissions, and retry.                                   |
| PROD-CTL-50002 | Target file not found.           | The expected output path, or its parent directory is missing.      | Create the necessary directories, verify the target path.                         |
| PROD-CTL-60001 | File remove failed.              | Permission was denied, or the file is in use.                      | Release any locks on the file, adjust permissions.                                |
| PROD-CTL-60002 | Open file failed.                | The file is missing, or access was denied.                         | Make sure the file exists, check permissions.                                     |
| PROD-CTL-60003 | Open stream failed.              | A pipe, socket, or file handle was not available.                  | Validate the endpoint, check permissions.                                         |
| PROD-CTL-60004 | File write failed.               | A short write or general IO error occurred.                        | Retry. Check the disk and filesystem health.                                      |
| PROD-CTL-60005 | File fsync failed.               | Flushing data to persistent storage failed.                        | Inspect the disk, check mount options, review kernel logs ( <code>dmesg</code> ). |
| PROD-CTL-60006 | File create failed.              | The parent directory is missing, or permissions are incorrect.     | Make sure the parent directory exists, fix <code>umask</code> or permissions.     |
| PROD-CTL-60007 | File rename failed.              | The source file does not exist, or permissions are insufficient.   | Make sure the source file exists, verify permissions. Retry.                      |
| PROD-CTL-60008 | Failed to mmap file.             | A memory-mapping error occurred, or the address space is low.      | Switch to buffered IO or reduce the mapped data size.                             |
| PROD-CTL-60009 | Failed to stat file.             | The path is invalid, or permissions are insufficient.              | Check the path and user permissions.                                              |
| PROD-CTL-70001 | Memory allocation failed.        | The system ran out of memory on a critical path.                   | Reduce parallelism or increase system memory limits.                              |
| PROD-CTL-70002 | Failed to create directory.      | The parent directory is missing, or permissions are insufficient.  | Create a parent directory, check permissions.                                     |
| PROD-CTL-70003 | Failed to open directory.        | The path is not a directory, or access was denied.                 | Make sure the path is a directory with proper access.                             |

## G.2. pgpro\_pwr — workload reports

The `pgpro_pwr` module is designed to discover most resource-intensive activities in your database. (PWR, pronounced like "power", is an abbreviation of Postgres Pro Workload Reporting.) This extension is based on Postgres Pro's [Statistics Collector](#) views and the [pgpro\\_stats](#) or [pg\\_stat\\_statements](#) extension.

### Note

Although `pgpro_pwr` can work with the `pg_stat_statements` extension, it is recommended that you use the `pgpro_stats` extension since it provides statement plans, wait events sampling and load distribution statistics for databases, roles, client hosts and applications.

Below, use of `pgpro_stats` is assumed unless otherwise noted.

If you cannot use `pgpro_stats` for an observed database, but the `pg_stat_kcache` extension is available, `pgpro_pwr` can process `pg_stat_kcache` data, which also provides information about CPU resource usage of statements and filesystem load (*rusage*).

`pgpro_pwr` can obtain summary wait statistics from the `pg_wait_sampling` extension. When `pg_wait_sampling` is in use, `pgpro_pwr` will reset the wait sampling profile on every sample.

`pgpro_pwr` is based on cumulative statistics sampling. Each sample contains statistic increments for most active objects and queries since the time when the previous sample was taken, or more concisely, *since the previous sample*. This data is later used to generate reports.

`pgpro_pwr` provides functions to collect samples. Regular sampling allows building a report on the database workload in the past.

`pgpro_pwr` allows you to take explicit samples during batch processing, load testing, etc.

Any time a sample is taken, `pgpro_stats_statements_reset()` (see `pgpro_stats` for the function description) is called to ensure that statement statistics will not be lost when the statements count exceed `pgpro_stats.max` (see [Section G.3.7.1](#)). The report will also contain a section informing you of whether the count of captured statements in any sample reaches 90% of `pgpro_stats.max`.

`pgpro_pwr` installed on one Postgres Pro server can also collect statistics from other servers. This feature is useful for gathering workload statistics from hot standbys on the primary server. To benefit from it, make sure that all server names and connection strings are specified and that the `pgpro_pwr` server can connect to all databases on all servers.

## G.2.1. pgpro\_pwr Architecture

The extension consists of the following parts:

- *Historical repository* is a storage for sampling data. The repository is a set of extension tables.

### Note

Among the rest, `pgpro_pwr` tables store query texts, which can contain sensitive information. So, for security reasons, restrict access to the repository as appropriate.

- *Sample management engine* comprises functions used to [take samples](#) and maintain the repository by removing obsolete sample data.
- *Report engine* comprises functions for [generating reports](#) based on data from the historical repository.
- *Administrative functions* allow you to create and manage [servers](#) and [baselines](#).

## G.2.2. Prerequisites

The prerequisites assume that `pgpro_pwr`, which is usually installed in a *target* cluster, i.e., the cluster that you will mainly track the workload for, the extension can also collect performance data from other clusters.

### G.2.2.1. For the pgpro\_pwr Database

The pgpro\_pwr extension depends on [PL/pgSQL](#) and the [dblink](#) extension.

### G.2.2.2. For the Target Server

The target server must allow connections to all databases from the server where pgpro\_pwr is running. To connect to the target server, provide a connection string where a particular database on this server is specified. This database is of high importance for pgpro\_pwr since the functionality of the [pgpro\\_stats](#) or [pg\\_stat\\_statements](#) extensions will be provided through this database. Note, however, that pgpro\_pwr will also connect to all the other databases on this server.

Optionally, for completeness of gathered statistics:

- If statement statistics are needed in reports, [pgpro\\_stats](#) must be installed and configured in the aforementioned database. The following settings may affect the completeness and accuracy of gathered statistics:

- `pgpro_stats.max`

Low setting of this parameter may cause some statement statistics to be wiped out before the sample is taken. A report will warn you if the value of `pgpro_stats.max` seems undersized.

- `pgpro_stats.track`

Avoid changing the default value of 'top' (note that the value of 'all' will affect the accuracy of %Total fields for statements-related sections of a report).

- Set the parameters of the Postgres Pro's [Statistics Collector](#) as follows:

```
track_activities = on
track_counts = on
track_io_timing = on
track_wal_io_timing = on    # Since PostgreSQL 14
track_functions = all/pl
```

## G.2.3. Installation and Setup

pgpro\_pwr is provided with Postgres Pro Enterprise as a separate pre-built package `pgpro-pwr-ent-14` (for the detailed installation instructions, see [Chapter 17](#)).

### Note

pgpro\_pwr creates a bunch of database objects, so installation in a dedicated schema is recommended.

Although the use of pgpro\_pwr with superuser privileges does not have any issues, superuser privileges are not necessary. So you can choose one of the following setup procedures depending on your configuration and security requirements or customize them to meet your needs:

### G.2.3.1. Simple Setup

Use this setup procedure when pgpro\_pwr is to be installed on the target cluster to only track its workload as superuser.

Create a schema for the pgpro\_pwr installation and create the extension:

```
CREATE SCHEMA profile;
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

### G.2.3.2. Complex Setup

Use this setup procedure when you intend to use `pgpro_pwr` for tracking workload on one or more servers and need to follow the principle of least privilege.

#### G.2.3.2.1. In the Target Server Database

Create a user for `pgpro_pwr` on the target server:

```
CREATE USER pwr_collector PASSWORD 'collector_pwd';
```

Make sure this user has permissions to connect to any database in the target cluster (by default, it is true) and that `pg_hba.conf` permits such a connection from the `pgpro_pwr` database host. Also, grant `pwr_collector` with membership in the `pg_read_all_stats` role and the `EXECUTE` privilege on the following functions:

```
GRANT pg_read_all_stats TO pwr_collector;  
GRANT EXECUTE ON FUNCTION pgpro_stats_statements_reset TO pwr_collector;  
GRANT EXECUTE ON FUNCTION pgpro_stats_totals_reset(text,bigint) TO pwr_collector;
```

Also ensure the `SELECT` privilege on the `pgpro_stats_archiver` view:

```
GRANT SELECT ON pgpro_stats_archiver TO pwr_collector;
```

#### G.2.3.2.2. In the `pgpro_pwr` Database

Create an unprivileged user:

```
CREATE USER pwr_user;
```

This user will be the owner of the extension schema and will collect samples.

Create a schema for the `pgpro_pwr` installation:

```
CREATE SCHEMA profile AUTHORIZATION pwr_user;
```

Grant the `USAGE` privilege on the schema where the `dblink` extension resides:

```
GRANT USAGE ON SCHEMA public TO pwr_user;
```

Create the extension using `pwr_user` account:

```
\c - pwr_user  
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

Define the connection parameters of the target server for `pgpro_pwr`. For example:

```
SELECT profile.create_server('target_server_name', 'host=192.168.1.100 dbname=postgres  
port=5432');
```

The connection string provided will be used in the `dblink_connect()` call while executing the `take_sample()` function.

#### Note

Connection strings are stored in a `pgpro_pwr` table in clear-text form. Make sure no other database users can access tables of the `pgpro_pwr` extension.

### G.2.3.3. Setting Up `pgpro_pwr` Roles

Up to three roles can be distinguished when `pgpro_pwr` is in operation:

- The *pgpro\_pwr owner* role is the owner of the `pgpro_pwr` extension.
- The *collecting role* is used by `pgpro_pwr` to connect to databases and collect statistics.
- The *reporting role* is used to generate reports.

If all the actions with `pgpro_pwr` are performed by the superuser role `postgres`, you can skip most of the setup explained below.

#### G.2.3.3.1. The `pgpro_pwr` Owner

This role can be used to perform all actions related to `pgpro_pwr`. This role will have access to server connection strings, which may contain passwords. You should use this role to call the `take_sample()` function. The `dblink` extension is needed for this user.

Consider an example assuming each extension in its own schema:

```
\c postgres postgres
CREATE SCHEMA dblink;
CREATE EXTENSION dblink SCHEMA dblink;
CREATE USER pwr_usr with password 'pwr_pwd';
GRANT USAGE ON SCHEMA dblink TO pwr_usr;
CREATE SCHEMA profile AUTHORIZATION pwr_usr;
\c postgres pwr_usr
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

#### G.2.3.3.2. The Collecting Role

This role should be used by `pgpro_pwr` to connect to databases and collect statistics. Unprivileged users cannot open connections using `dblink` without a password, so you need to provide the password in the connection string for each server. This role should have access to all supported statistics extensions. It should also be able to perform a reset of statistics extensions.

Consider an example. If you use `pgpro_stats` to collect statistics, set up the collecting role as follows:

```
\c postgres postgres
CREATE SCHEMA pgps;
CREATE EXTENSION pgpro_stats SCHEMA pgps;
CREATE USER pwr_collector with password 'collector_pwd';
GRANT pg_read_all_stats TO pwr_collector;
GRANT USAGE ON SCHEMA pgps TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgps.pgpro_stats_statements_reset TO pwr_collector;
```

If you use `pg_stat_statements` to collect statistics, set up the collecting role as follows:

```
\c postgres postgres
CREATE SCHEMA pgss;
CREATE SCHEMA pgsk;
CREATE SCHEMA pgws;
CREATE EXTENSION pg_stat_statements SCHEMA pgss;
CREATE EXTENSION pg_stat_kcache SCHEMA pgsk;
CREATE EXTENSION pg_wait_sampling SCHEMA pgws;
CREATE USER pwr_collector with password 'collector_pwd';
GRANT pg_read_all_stats TO pwr_collector;
GRANT USAGE ON SCHEMA pgss TO pwr_collector;
GRANT USAGE ON SCHEMA pgsk TO pwr_collector;
GRANT USAGE ON SCHEMA pgws TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgss.pg_stat_statements_reset TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgsk.pg_stat_kcache_reset TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgws.pg_wait_sampling_reset_profile TO pwr_collector;
```

Now you should set up a connection string pointing to the database with statistics extensions installed:

```
\c postgres pwr_usr
SELECT profile.set_server_connstr('local','dbname=postgres port=5432 host=localhost
user=pwr_collector password=collector_pwd');
```

Password authentication must be configured in the `pg_hba.conf` file for the `pwr_collector` user.

Obviously, the collecting role should be properly configured on all servers observed by `pgpro_pwr`.

Now you should be able to call `take_sample()` using the `pwr_usr` role:

```
\c postgres pwr_usr
SELECT * FROM take_sample();
```

And now it's time to configure the scheduler (in our example, the `crontab` command of the `postgres` user):

```
*/30 * * * *    psql -U pwr_usr -d postgres -c 'SELECT profile.take_sample()' > /dev/
null 2>&1
```

Note that you can use the Postgres Pro password file to store passwords.

#### G.2.3.3.3. The Reporting Role

Any user can build a `pgpro_pwr` report. The minimal privileges needed to generate `pgpro_pwr` reports are granted to the `public` role. However a full report, with query texts, is only available to the member of the `pg_read_all_stats` role. Anyway, the reporting role cannot access server connection strings, so it cannot get the passwords of servers.

#### G.2.3.3.4. Setting Extension Parameters

In `postgresql.conf`, you can define the following `pgpro_pwr` parameters:

`pgpro_pwr.max (integer)`

Number of top objects (statements, relations, etc.) to be reported in each sorted report table. This parameter affects the size of a sample: the more objects you want to appear in your report, the more objects we need to keep in a sample. The maximum value is 100. Any larger value is lowered to 100.

The default value is 20.

`pgpro_pwr.max_sample_age (integer)`

Retention time of the sample, in days. Samples aged `pgpro_pwr.max_sample_age` days and older are automatically deleted on the next `take_sample()` call.

The default value is 7 days.

`pgpro_pwr.max_query_length (integer)`

Maximum query length allowed in reports. All queries in a report will be truncated to `pgpro_pwr.max_query_length` characters.

The default value is 20 000 characters.

`pgpro_pwr.track_sample_timings (boolean)`

Enables collecting detailed timing statistics of `pgpro_pwr`'s own sampling procedures. Set this parameter to diagnose why sampling functions run slowly. Collected timing statistics will be available in the `v_sample_timings` view.

The default value is `off`.

`pgpro_pwr.statements_reset (boolean)`

Controls the `pgpro_stats/pg_stat` statements statistics reset during taking a sample. Allows you not to reset the statistics during taking a sample due to new techniques employed. When disabled, `pgpro_pwr` will track statement evictions using the value of the `calls` field. However this method does not completely prevent statistics loss. `pg_stat_statements` v1.11 and `pgpro_stats` v1.8 contain time tracking abilities that can reduce the possible data loss. When this setting is disabled, you can temporarily enable it in a session if you want to sometimes perform a reset of `pgpro_stats/pg_stat` statements.

The default value is `on`.

`pgpro_pwr.relsizes_collect_mode (text)`

Defines the mode of collecting relation sizes. Possible values:

- `off` — collection of relation sizes is based on `pg_class`. Although the relation sizes collected this way are rough, their collection consumes almost no resources.
- `on` — accurate relation sizes are collected for each sample using the `pg_relation_size()` function, which requires a lock on the table and is pretty resource intensive.
- `schedule` — accurate relation sizes are collected in the size-collection window, defined for each server.

The default value is `off`.

## G.2.4. Managing Servers

Once installed, `pgpro_pwr` creates one enabled `local` server for the current cluster. If a server is *enabled*, `pgpro_pwr` includes it in sampling when no server is explicitly specified (see `take_sample()` for details). A server that is not enabled is referred to as *disabled*.

The default connection string for a local node contains only `dbname` and `port` parameters. The values of these parameters are taken from the connection used to create the extension. You can change the server connection string using the `set_server_connstr()` function when needed.

### G.2.4.1. Server Management Functions

Use the following `pgpro_pwr` functions for server management:

```
create_server(server name, connstr text, enabled boolean DEFAULT TRUE, max_sample_age
integer DEFAULT NULL description text DEFAULT NULL)
```

Creates a server definition.

Arguments:

- `server` — server name. Must be unique.
- `connstr` — connection string. Must contain all the necessary settings to connect from `pgpro_pwr` server to the target server database.
- `enabled` — set to include the server in sampling by the `take_sample()` function without arguments.
- `max_sample_age` — retention time of the sample. Overrides the global `pgpro_pwr.max_sample_age` setting for this server.
- `description` — server description text, to be included in reports.

Here is an example of how to create a server definition:

```
SELECT profile.create_server('omega','host=192.168.1.100 dbname=postgres
port=5432');
```

```
drop_server(server name)
```

Drops a server and all its samples.

```
set_server_description(server name description text)
```

Sets a new server description.

```
set_server_subsampling(server name, subsample_enabled boolean, min_query_duration inter-
val, min_xact_duration interval, min_xact_age integer, min_idle_xact_dur interval hour
to second)
```

Defines subsample settings for a server.

Arguments:

- *server* — server name.
- *subsample\_enabled* — defines whether subsampling is enabled for the server, that is, whether `take_subsample()` function should actually take a subsample.
- *min\_query\_duration* — the query duration threshold.
- *min\_xact\_duration* — the transaction duration threshold.
- *min\_xact\_age* — the transaction age threshold.
- *min\_idle\_xact\_dur\_age* — the idle transaction threshold.

`enable_server(server name)`

Includes a server in sampling by the `take_sample()` function without arguments.

`disable_server(server name)`

Excludes a server from sampling by the `take_sample()` function without arguments.

`rename_server(server name, new_name name)`

Renames a server.

`set_server_max_sample_age(server name, max_sample_age integer)`

Sets the retention period for a server (in days). To reset the server retention, set the value of *max\_sample\_age* to NULL.

`set_server_db_exclude(server name, exclude_db name[])`

Excludes a list of databases on a server from sampling. Use when `pgpro_pwr` is unable to connect to some databases in a cluster (for example, in Amazon RDS instances).

`set_server_connstr(server name, server_connstr text)`

Sets the connection string for a server.

`set_server_setting(server name, setting text, value jsonb)`

Fine-tunes settings of the server statistics collection. *collect\** settings control which statistics should be collected, and *value* for these settings accepts boolean values, with the default equal to true. Available settings:

- *collect\_pg\_stat\_statement* — collect statement statistics using `pg_stat_statements` and `pg_stat_kcache` extensions.
- *collect\_pg\_wait\_sampling* — collect wait event statistics using the `pg_wait_sampling` extension.
- *collect\_objects* — collect all the schema object statistics, that is, tables, indexes, and functions, from `pg_stat_*` views.
- *collect\_relations* — collect statistics on tables and indexes from `pg_stat_*` views.
- *collect\_functions* — collect statistics on user functions from the `pg_stat_user_functions` view.
- *collect\_vacuum\_stats* — collect the extended vacuum statistics.

`show_server_settings(server name)`

Returns the statistics collection settings for the specified server.

`show_servers()`

Displays the list of configured servers.

## G.2.5. Managing Samples

A *sample* contains the database workload statistics since the previous sample

### G.2.5.1. Sampling Functions

The following `pgpro_pwr` functions relate to sampling:

```
take_sample()  
take_sample(server name [, skip_sizes boolean])
```

Takes samples.

If the parameter is omitted, the function takes a sample on each enabled server. Servers are accessed for sampling sequentially, one by one. The function returns a table with the following columns:

- `server` — server name.
- `result` — result of taking the sample. Can be `OK` if the sample was taken successfully or contain the error trace text in case of exception.
- `elapsed` — time elapsed while the sample was taken.

If called with the parameter, the function takes a sample on the specified server even if this server is disabled. Use when you need different sampling frequencies on specific servers. Returns 0 on success.

Arguments:

- `server` — server name.
- `skip_sizes` — if omitted or set to null, the size-collection policy applies; if `false`, relation sizes are collected; if `true`, the collection of relation sizes is skipped.

```
take_sample_subset([sets_cnt integer, current_set integer])
```

Takes a sample on each server in a subset of servers. Use to take samples on servers in parallel if you have many enabled servers. Although PL/pgSQL does not support parallel execution, you can call this function in parallel sessions. This function returns the same type as `take_sample()`. If both parameters are omitted, the function behaves like the `take_sample()` function, i.e., it takes a sample on all enabled servers one by one.

Arguments:

- `sets_cnt` — number of subsets to divide all enabled servers into.
- `current_set` — number of the subset to collect samples for. Takes values from 0 through `sets_cnt - 1`. For the specified subset, samples are collected as usual, server by server.

If a reset of statistics since the previous sample was detected, `pgpro_pwr` treats corresponding absolute values as differentials; however, the accuracy will be affected anyway.

```
show_samples([server name,] [days integer])
```

Returns a table with information on server samples (local server is assumed if `server` is omitted) for the last `days` days (all existing samples are assumed if omitted). This table has the following columns:

- `sample` — sample identifier.
- `sample_time` — time when this sample was taken.
- `dbstats_reset` — NULL or the statistics reset timestamp of the `pg_stat_database` view if the statistics were reset since the previous sample.
- `clustats_reset` — NULL or the statistics reset timestamp of the `pg_stat_bgwriter` view if the statistics were reset since the previous sample.
- `archstats_reset` — NULL or the statistics reset timestamp of the `pg_stat_archiver` view if the statistics were reset since the previous sample.

Sampling functions also maintain the server repository by deleting obsolete samples and baselines according to the retention policy.

### G.2.5.2. Taking Samples

To take samples for all enabled servers, call the `take_sample()` function. Usually, one or two samples per hour is sufficient. You can use a cron-like tool to schedule sampling. Here is an example for a 30-minute sampling period:

```
*/30 * * * * psql -c 'SELECT profile.take_sample()' &> /dev/null
```

However, the results of such a call are not checked for errors. In a production environment, function results can be used for monitoring. This function returns OK for all servers with successfully taken samples and shows error text for failed servers:

```
SELECT * FROM take_sample();
   server   |                                     result
   | elapsed
-----+-----
+-----+-----
ok_node    | OK
| 00:00:00.48
fail_node  | could not establish connection
+| 00:00:00
| SQL statement "SELECT dblink_connect('server_connection',server_connstr)"
+|
| PL/pgSQL function take_sample(integer) line 69 at PERFORM
+|
| PL/pgSQL function take_sample_subset(integer,integer) line 27 at
assignment+|
| SQL function "take_sample" statement 1
+|
| FATAL:  database "postgresno" does not exist
|
(2 rows)
```

### G.2.5.3. Sample Retention Policy

You can define sample retention at the following levels:

#### 1. Global

The value of the `pgpro_pwr.max_sample_age` parameter in the `postgresql.conf` file defines a common retention setting, which is effective if none of other related settings are defined.

#### 2. Server

Specifying the `max_sample_age` parameter while creating a server or calling the `set_server_max_sample_age(server,max_sample_age)` function for an existing server defines the retention for the server. A server retention setting overrides `pgpro_pwr.max_sample_age` for a specific server.

#### 3. Baseline

A [baseline](#) created overrides all the other retention periods for included samples.

## G.2.6. Managing the Collection of Relation Sizes

It may take considerable time to collect sizes of all relations in a database by Postgres Pro relation-size functions. Besides, those functions require `AccessExclusiveLock` on a relation. However, it may be sufficient for you to collect relation sizes on a daily basis. `pgpro_pwr` allows you to skip collecting relation sizes by defining the *size-collection policy* for servers. The policy defines:

- A daily window when the collection of relation sizes is permitted.
- A minimum gap between two samples with relation sizes collected.

When the size-collection policy is defined, sampling functions collect relation sizes only when the sample is taken in the defined window and the previous sample with sizes is older than the gap. The following function defines this policy:

```
set_server_size_sampling(server name, window_start time with time zone DEFAULT NULL,
window_duration interval hour to second DEFAULT NULL, sample_interval interval day to
minute DEFAULT NULL, collect_mode text DEFAULT NULL)
```

Defines the size-collection policy for a server.

Arguments:

- *server* — server name.
- *window\_start* — start time of the size-collection window.
- *window\_duration* — duration of the size-collection window.
- *sample\_interval* — minimum time gap between two samples with relation sizes collected.
- *collect\_mode* — when set to `off`, which is the default for new installations, relation sizes are collected from `pg_class`, when set to `on`, relation sizes are collected using the `pg_relation_size()` function, when set to `schedule`, `pgpro_pwr` collects the relation size in the size-collection window. This parameter overrides the `relnsize_collect_mode` extension parameter. Upgrading from a previous version sets the value of this parameter to `on` or `schedule`, so the previous behavior does not change.

### Note

When you build a report between samples either of which lacks relation-size data, relation-growth sections will be based on `pg_class.relpages` data. However, you can expand the report interval bounds to the nearest samples with relation sizes collected using the `with_growth` parameter of [report generation functions](#); this makes the growth data more accurate.

Relation sizes are needed to calculate sequentially scanned volume for tables and explicit vacuum load for indexes.

Example:

```
SELECT set_server_size_sampling('local','23:00+03',interval '2 hour',interval '8 hour',
'schedule');
```

The `show_servers_size_sampling` function shows size collection policies for all servers:

```
postgres=# SELECT * FROM show_servers_size_sampling();
 server_name | window_start | window_end | window_duration | sample_interval |
limited_collection
-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----
 local      | 23:00:00+03 | 01:00:00+03 | 02:00:00        | 08:00:00        | t
```

## G.2.7. Managing Subsamples

Some performance-related data available in Postgres Pro is not cumulative. For example, the most often used data about session states is available through the `pg_stat_activity` view and can only be obtained with frequent samples. However, the `take_sample()` function is heavy and can take considerable amount of time. So it is not suitable for collecting session state data.

The *subsample* feature provides a new fast `take_subsample()` function. It can be used to collect relatively fast changing data. Every subsample is bound to the next regular sample and is deleted by the retention policy together with it.

The subsample feature can be used to capture the most interesting session states:

- Long running queries
- Long transactions
- Aged transactions, that is, those that hold a snapshot behind a lot of other transactions
- Transactions being in an idle state for a long time

### G.2.7.1. Subsampling Functions

The following `pgpro_pwr` functions relate to subsampling:

```
take_subsample()  
take_subsample(server name)
```

If the parameter is omitted, the function takes a subsample on each *enabled* server with subsampling enabled (see [set\\_server\\_subsampling](#) for details). Server subsamples are taken sequentially, one by one. The function returns a table with the following columns:

- `server` — server name.
- `result` — result of taking the subsample. Can be `OK` if the subsample was taken successfully or contain the error text in case of exception.
- `elapsed` — time elapsed while the subsample was taken.

This tabular return format makes it easy to control subsample creation using an SQL query.

If called with the parameter, the function takes a subsample for the specified server. Use when you need different subsampling frequencies on servers or if you want to take an explicit subsample on a specific server.

Arguments:

- `server` — server name.

#### Note

Trying to take a subsample during taking a sample fails.

```
take_subsample_subset([sets_cnt integer], [current_set integer])
```

Takes subsamples for a subset of enabled servers with subsampling enabled. Although subsamples should be fast enough for serial processing, subsamples can be taken in parallel, like regular samples. This function returns the same type as `take_subsample()`. If both parameters are omitted, the function behaves like the `take_subsample()` function.

Arguments:

- `sets_cnt` — number of server subsets.
- `current_set` — the subset to process. Takes values from 0 through `sets_cnt - 1`. For the specified subset, subsamples are collected as usual, server by server.

### G.2.7.2. Configuring the Subsample Feature

The following settings affect the subsample behaviour:

- `pgpro_pwr.subsample_enabled` — defines whether the `take_subsample()` function should actually take a subsample.
- `pgpro_pwr.min_query_duration` — the long running query threshold.
- `pgpro_pwr.min_xact_duration` — the long transaction threshold.
- `pgpro_pwr.min_xact_age` — the transaction age threshold.

- `pgpro_pwr.min_idle_xact_dur_age` — the idle transaction threshold.

The subsample behavior can be defined at the server level using the [set\\_server\\_subsampling](#) function.

The last observed session state is saved in the repository when either of the following threshold-related events happens:

- During query execution, the difference between `now()` and the `query_start` exceeds the `pgpro_pwr.min_query_duration` threshold.
- During a transaction, the difference between `now()` and the `xact_start` exceeds the `pgpro_pwr.min_xact_duration` threshold.
- During a transaction, the `age(backend_xmin)` exceeds the `pgpro_pwr.min_xact_age` threshold.
- During a transaction in a state `idle in transaction` or `idle in transaction (aborted)`, the difference between `now()` and the `state_change` exceeds the `pgpro_pwr.min_idle_xact_duration` threshold.

See [Chapter 27](#) for details of the mentioned fields. Every subsample can hold at most `pgpro_pwr.max` entries for every threshold type.

### G.2.7.3. Scheduling Subsamples

Subsamples are fast enough to take them quite often. However usually you do not need more than 2-4 subsamples per minute. Obviously the subsample frequency depends on the shortest used duration of a threshold setting.

Cron only allows one call per minute, so some effort is needed to schedule more frequent subsamples. For example, the `\watch psql` command can be used:

```
echo "select take_subsample(); \watch 15" | psql &> /dev/null
```

The `psql` call can be wrapped in the `systemd` service like this:

```
Description=pgpro_pwr subsampling unit
[Unit]

[Service]
Type=simple
ExecStart=/bin/sh -c 'echo "select take_subsample(); \watch 15" | /path/to/psql -qo /dev/null'
User=postgres
Group=postgres

[Install]
WantedBy=multi-user.target
```

## G.2.8. Managing Baselines

A *baseline* is a named sequence of samples that has its own retention setting. A baseline can be used as a sample interval in report generation functions. An undefined baseline retention means infinite retention. Use baselines to save information about the database workload for a certain time interval.

### G.2.8.1. Baseline Management Functions

Use the following `pgpro_pwr` functions for baseline management:

```
create_baseline([server name,] baseline varchar(25), start_id integer, end_id integer [,
days integer])
create_baseline([server name,] baseline varchar(25), time_range tstzrange [, days in-
teger])
```

Creates a baseline.

Arguments:

- *server* — server name. *local* sever is assumed if omitted.
- *baseline* — baseline name. Must be unique for a server.
- *start\_id* — identifier of the first sample in the baseline.
- *end\_id* — identifier of the last sample in the baseline.
- *time\_range* — time interval for the baseline. The baseline will include all samples for the minimal interval that covers *time\_range*.
- *days* — baseline retention time, defined in integer days since `now()`. Omit or set to null for infinite retention.

```
drop_baseline([server name,] baseline varchar(25))
```

Drops a baseline. For the meaning and usage details of function arguments, see [create\\_baseline](#). Dropping a baseline does not mean dropping all its samples immediately. The baseline retention just no longer applies to them.

```
keep_baseline([server name,] baseline varchar(25) [, days integer])
```

Changes the retention of a baseline. For the meaning and usage details of function arguments, see [create\\_baseline](#). Omit the *baseline* parameter or pass null to it to change the retention of all existing baselines.

```
show_baselines([server name])
```

Displays existing baselines. Call `show_baselines` to get information about the baselines, such as names, sampling intervals and retention periods. *local* sever is assumed if the *server* parameter is omitted.

## G.2.9. Data Export and Import

Collected samples can be exported from one instance of the `pgpro_pwr` extension and then loaded into another one. This feature helps you to move server data from one instance to another or to send collected data to your support team.

### G.2.9.1. Data Export

The [export\\_data](#) function exports data to a regular table. You can use any method available to export this table from your database. For example, you can use the `\copy` meta-command of [psql](#) to obtain a single `csv` file:

```
postgres=# \copy (select * from export_data()) to 'export.csv'
```

### G.2.9.2. Data Import

Since data can only be imported from a local table, first, load the data you exported. Using the `\copy` meta-command again:

```
postgres=# CREATE TABLE import (section_id bigint, row_data json);
CREATE TABLE
postgres=# \copy import from 'export.csv'
COPY 6437
```

Now you can import the data by providing the `import` table to the [import\\_data](#) function:

```
postgres=# SELECT * FROM import_data('import');
```

After successful import, you can drop the `import` table.

### Note

If server data is imported for the first time, your local `pgpro_pwr` servers with matching names will cause a conflict during import. To avoid this, you can temporarily rename such servers or you can specify the server name prefix for import operations. However, during import of new data for already imported servers, they are matched by system identifiers, so feel free to rename imported

severs. Also keep in mind that `pgpro_pwr` sets servers being imported to the *disabled* state for `take_sample()` to bypass them.

### G.2.9.3. Export and Import Functions

Use these functions to export or import data:

```
export_data([server name, [min_sample_id integer,] [max_sample_id integer,]] [, obfus-  
cate_queries boolean] [, hide_connstr boolean])
```

Exports collected data.

Arguments:

- *server* — server name. All configured servers are assumed if omitted.
- *min\_sample\_id*, *max\_sample\_id* — sample identifiers to bound the export (inclusive). If *min\_sample\_id* is omitted or set to null, all samples until *max\_sample\_id* sample are exported; if *max\_sample\_id* is omitted or set to null, all samples since *min\_sample\_id* sample are exported.
- *obfuscate\_queries* — exports query texts as MD5 hash and excludes server connection strings from export. Pass this argument only when you want to hide query texts.
- *hide\_connstr* — excludes server connection strings from export.

```
import_data(data regclass [, server_name_prefix text])
```

Imports previously exported data. Returns the number of actually loaded rows in `pgpro_pwr` tables.

Arguments:

- *data* is the name of the table containing import data.
- *server\_name\_prefix* specifies the server name prefix for the import operation. It can be used to avoid name conflicts.

## G.2.10. Report Generation Functions

`pgpro_pwr` reports are generated in HTML format by reporting functions. The following types of reports are available:

- *Regular reports* provide statistics on the workload for an interval.
- *Differential reports* provide statistics on the same objects for two intervals. Corresponding values are located next to each other, which makes it easy to compare the workloads.

Reporting functions take sample identifiers, baselines or time ranges to determine the intervals. For time ranges, these are the minimal intervals that cover the ranges.

### G.2.10.1. Regular Reports

Use these functions to generate regular reports:

```
get_report([server name,] start_id integer, end_id integer [, description text [,  
with_growth boolean [, db_exclude name[ ]]])  
get_report([server name,] time_range tstzrange [, description text [, with_growth boolean  
[, db_exclude name[ ]]])  
get_report([server name,] baseline varchar(25) [, description text [, with_growth boolean  
[, db_exclude name[ ]]])
```

Generates a regular report defined by the arguments.

Arguments:

- *server* — server name. local sever is assumed if omitted.
- *start\_id* — identifier of the interval starting sample.

- *end\_id* — identifier of the interval ending sample.
- *baseline* — baseline name.
- *time\_range* — time range.
- *description* — short text to be included in the report as its description.
- *with\_growth* — flag requesting interval expansion to the nearest bounds with data on relation growth available. The default value is *false*.
- *db\_exclude* — the database exclusion list. Lists databases to be excluded from all report tables having the *Database* column. Use to hide some databases in the report.

```
get_report_latest([server name,])  
get_report_latest([server name [, db_exclude name[]]])
```

Generates a regular report for two latest samples.

Arguments:

- *server* — server name. *local* sever is assumed if omitted.
- *db\_exclude* — the database exclusion list. Lists databases to be excluded from all report tables having the *Database* column. Use to hide some databases in the report.

### G.2.10.2. Differential Reports

Use this function to generate differential reports:

```
get_diffreport([server name,] start1_id integer, end1_id integer, start2_id integer,  
end2_id integer [, description text [, with_growth boolean [, db_exclude name[]]])  
get_diffreport([server name,] time_range1 tstzrange, time_range2 tstzrange [, description  
text [, with_growth boolean [, db_exclude name[]]])  
get_diffreport([server name,] baseline1 varchar(25), baseline2 varchar(25) [, description  
text [, with_growth boolean [, db_exclude name[]]])  
get_diffreport([server name,] baseline1 varchar(25), time_range2 tstzrange [, description  
text [, with_growth boolean[, db_exclude name[]]])  
get_diffreport([server name,] time_range1 tstzrange, baseline2 varchar(25) [, description  
text [, with_growth boolean[, db_exclude name[]]])  
get_diffreport([server name,] start1_id integer, end1_id integer, baseline2 varchar(25)  
[, description text [, with_growth boolean[, db_exclude name[]]])  
get_diffreport([server name,] baseline1 varchar(25), start2_id integer, end2_id integer  
[, description text [, with_growth boolean[, db_exclude name[]]])
```

Generates a differential report for two intervals. The combinations of arguments provide possible ways to specify the two intervals.

Arguments:

- *server* — server name. *local* sever is assumed if omitted.
- *start1\_id, end1\_id* — identifiers of the starting and ending samples for the first interval.
- *start2\_id, end2\_id* — identifiers of the starting and ending samples for the second interval.
- *baseline1* — baseline name for the first interval.
- *baseline2* — baseline name for the second interval.
- *time\_range1* — time range for the first interval.
- *time\_range2* — time range for the second interval.
- *description* — short text to be included in the report as its description.
- *with\_growth* — flag requesting interval expansion to the nearest bounds with data on relation growth available. The default value is *false*.

- *db\_exclude* — the database exclusion list. Lists databases to be excluded from all report tables having the `Database` column. Use to hide some databases in the report.

### G.2.10.3. Report Generation Example

Generate a report for the `local` server and interval defined by samples:

```
psql -Aqtc "SELECT profile.get_report(480,482)" -o report_480_482.html
```

For any other server, provide its name:

```
psql -Aqtc "SELECT profile.get_report('omega',12,14)" -o report_omega_12_14.html
```

Generate a report using time ranges:

```
psql -Aqtc "SELECT profile.get_report(tstzrange('2020-05-13 11:51:35+03','2020-05-13 11:52:18+03'))" -o report_range.html
```

Generate a relative time-range report:

```
psql -Aqtc "SELECT profile.get_report(tstzrange(now() - interval '1 day',now()))" -o report_last_day.html
```

## G.2.11. pgpro\_pwr Report Sections

Each `pgpro_pwr` report is divided into sections, described below. The number of top objects reported in each sorted report table is specified by the `pgpro_pwr.max` parameter.

Almost every item in the report can be accentuated by a single mouse click. The accentuated item will be instantly highlighted in all report sections, making it easy to find. The attributes identifying the item will appear in the bottom-right corner of the page. For example, if you click on a database name in the “Database statistics” report table, you can notice a small table with the database attributes in the bottom-right corner of the page.

When you scroll down the report, its table of contents will be available on the right side of the page. It can be hidden with a single mouse click on the “content” tag.

A substring-based filter is also available that helps limit the report contents to particular objects based on a substring. Specifically, substring-based filtering is applied to query texts.

### G.2.11.1. Server statistics

Tables in this section of a `pgpro_pwr` report are described below.

The report table “Database statistics” provides per-database statistics for the report interval. The statistics are based on the `pg_stat_database` view. [Table G.3](#) lists columns of this report table.

**Table G.3. Database statistics**

| Column            | Description                                                                                                                                                                   | Field/Calculation              |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------|
| Database          | Database name                                                                                                                                                                 | <code>datname</code>           |
| Commits           | Number of committed transactions                                                                                                                                              | <code>xact_commit</code>       |
| Rollbacks         | Number of rolled back transactions                                                                                                                                            | <code>xact_rollback</code>     |
| Deadlocks         | Number of deadlocks detected                                                                                                                                                  | <code>deadlocks</code>         |
| Checksum Failures | Number of data page checksum failures detected in this database. This field is only shown if any checksum failures were detected in this database during the report interval. | <code>checksum_failures</code> |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Column                    | Description                                                                                                                                                                                   | Field/Calculation                                    |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|
| Checksums Last            | Time at which the last data page checksum failure was detected in this database. This field is only shown if any checksum failures were detected in this database during the report interval. | checksum_last_failure                                |
| Hit%                      | Buffer cache hit ratio, i.e., percentage of pages fetched from buffers in all pages fetched                                                                                                   |                                                      |
| Read                      | Number of disk blocks read in this database                                                                                                                                                   | blks_read                                            |
| Hit                       | Number of times disk blocks were found already in the buffer cache                                                                                                                            | blks_hit                                             |
| Ret                       | Number of returned tuples                                                                                                                                                                     | tup_returned                                         |
| Fet                       | Number of fetched tuples                                                                                                                                                                      | tup_fetched                                          |
| Ins                       | Number of inserted tuples                                                                                                                                                                     | tup_inserted                                         |
| Upd                       | Number of updated tuples                                                                                                                                                                      | tup_updated                                          |
| Del                       | Number of deleted tuples                                                                                                                                                                      | tup_deleted                                          |
| Planned Parallel workers  | Number of parallel workers planned to be launched by queries on this database                                                                                                                 |                                                      |
| Launched Parallel workers | Number of parallel workers launched by queries on this database                                                                                                                               |                                                      |
| Temp Size                 | Total amount of data written to temporary files by queries in this database                                                                                                                   | temp_bytes                                           |
| Temp Files                | Number of temporary files created by queries in this database                                                                                                                                 | temp_files                                           |
| Size                      | Database size at the time of the last sample in the report interval                                                                                                                           | pg_database_size()                                   |
| Growth                    | Database growth during the report interval                                                                                                                                                    | pg_database_size() increment between interval bounds |

The report table “Cluster I/O statistics” provides I/O statistics by object types, backend types and contexts. This table is based on the `pg_stat_io` view of the [Cumulative Statistics System](#), available since Postgres Pro 16. [Table G.4](#) lists columns of this report table. Times are provided in seconds.

**Table G.4. Cluster I/O statistics**

| Column      | Description                                         |
|-------------|-----------------------------------------------------|
| Object      | Target object of an I/O operation                   |
| Backend     | Type of the backend that performed an I/O operation |
| Context     | The context of an I/O operation                     |
| Reads Count | Number of read operations                           |
| Reads Bytes | Amount of data read                                 |
| Reads Time  | Time spent in read operations                       |

| Column           | Description                                                                                                                                                                          |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Writes Count     | Number of write operations                                                                                                                                                           |
| Writes Bytes     | Amount of data written                                                                                                                                                               |
| Writes Time      | Time spent in write operations                                                                                                                                                       |
| Writebacks Count | Number of blocks which the process requested the kernel write out to permanent storage                                                                                               |
| Writebacks Bytes | Amount of data requested for write out to permanent storage                                                                                                                          |
| Writebacks Time  | Time spent in writeback operations, including the time spent queueing write-out requests and, potentially, the time spent to write out the dirty data                                |
| Extends Count    | Number of relation extend operations                                                                                                                                                 |
| Extends Bytes    | Amount of space used by extend operations                                                                                                                                            |
| Extends Time     | Time spent in extend operations                                                                                                                                                      |
| Hits             | The number of times a desired block was found in a shared buffer                                                                                                                     |
| Evictions        | Number of times a block has been written out from a shared or local buffer in order to make it available for another use                                                             |
| Reuses           | The number of times an existing buffer in a size-limited ring buffer outside of shared buffers was reused as part of an I/O operation in the bulkread, bulkwrite, or vacuum contexts |
| Fsyncs Count     | Number of fsync calls. These are only tracked in context normal.                                                                                                                     |
| Fsyncs Time      | Time spent in fsync operations                                                                                                                                                       |

The report table “Cluster SLRU statistics” provides access statistics on SLRU (simple least-recently-used) caches. This table is based on the `pg_stat_slru` view of the [Cumulative Statistics System](#). [Table G.5](#) lists columns of this report table. Times are provided in seconds.

**Table G.5. Cluster SLRU statistics**

| Column | Description                                                                                                                                                                      | Field/Calculation                                                 |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------|
| Name   | Name of the SLRU                                                                                                                                                                 | <code>name</code>                                                 |
| Zeroed | Number of blocks zeroed during initializations                                                                                                                                   | <code>blks_zeroed</code>                                          |
| Hits   | Number of times disk blocks were found already in the SLRU, so that a read was not necessary (this only includes hits in the SLRU, not the operating system's file system cache) | <code>blks_hit</code>                                             |
| Reads  | Number of disk blocks read for this SLRU                                                                                                                                         | <code>blks_read</code>                                            |
| %Hit   | Number of disk block hits for this SLRU as the percentage of Reads + Hits                                                                                                        | $\text{blks\_hit} * 100 / (\text{blks\_read} + \text{blks\_hit})$ |
| Writes | Number of disk blocks written for this SLRU                                                                                                                                      | <code>blks_written</code>                                         |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Column    | Description                                          | Field/Calculation |
|-----------|------------------------------------------------------|-------------------|
| Checked   | Number of blocks checked for existence for this SLRU | blks_exists       |
| Flushes   | Number of flushes of dirty data for this SLRU        | flushes           |
| Truncates | Number of truncates for this SLRU                    | truncates         |

Table “Session statistics by database” is available in the report for Postgres Pro databases starting with version 14. This table is based on the `pg_stat_database` view of the [Statistics Collector](#). [Table G.6](#) lists columns of this report table. Times are provided in seconds.

**Table G.6. Session statistics by database**

| Column               | Description                                                                                                                                                                                                                              | Field/Calculation        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| Database             | Database name                                                                                                                                                                                                                            |                          |
| Timing Total         | Time spent by database sessions in this database during the report interval (note that statistics are only updated when the state of a session changes, so if sessions have been idle for a long time, this idle time won't be included) | session_time             |
| Timing Active        | Time spent executing SQL statements in this database during the report interval (this corresponds to the states <code>active</code> and <code>fastpath function call</code> in <code>pg_stat_activity</code> )                           | active_time              |
| Timing Idle(T)       | Time spent idling while in a transaction in this database during the report interval (this corresponds to the states <code>idle in transaction</code> and <code>idle in transaction (aborted)</code> in <code>pg_stat_activity</code> )  | idle_in_transaction_time |
| Sessions Established | Total number of sessions established to this database during the report interval                                                                                                                                                         | sessions                 |
| Sessions Abandoned   | Number of database sessions to this database that were terminated because connection to the client was lost during the report interval                                                                                                   | sessions_abandoned       |
| Sessions Fatal       | Number of database sessions to this database that were terminated by fatal errors during the report interval                                                                                                                             | sessions_fatal           |
| Sessions Killed      | Number of database sessions to this database that were terminated by operator intervention during the report interval                                                                                                                    | sessions_killed          |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

In Postgres Pro Enterprise databases of versions that include [pgpro\\_stats](#) version starting with 1.4, workload statistics of vacuum processes are available. The “Database vacuum statistics” report table provides per-database aggregated total vacuum statistics based on the `pgpro_stats_vacuum_tables` view. [Table G.7](#) lists columns of this report table. Times are provided in seconds.

**Table G.7. Database vacuum statistics**

| Column         | Description                                                                                                                                                                        | Field/Calculation                                                  |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|
| Database       | Database name                                                                                                                                                                      |                                                                    |
| Blocks fetched | Total number of database blocks fetched by vacuum operations                                                                                                                       | <code>total_blks_read + total_blks_hit</code>                      |
| %Total         | Total number of database blocks fetched (read+hit) by vacuum operations as the percentage of all blocks fetched in the cluster                                                     | <code>Blocks fetched * 100 / Cluster fetched</code>                |
| Blocks read    | Total number of database blocks read by vacuum operations                                                                                                                          | <code>total_blks_read</code>                                       |
| %Total         | Total number of database blocks read by vacuum operations as the percentage of all blocks read in the cluster                                                                      | <code>Blocks read * 100 / Cluster read</code>                      |
| VM Frozen      | Total number of blocks marked all-frozen in the visibility map                                                                                                                     | <code>pages_frozen</code>                                          |
| VM Visible     | Total number of blocks marked all-visible in the visibility map                                                                                                                    | <code>pages_all_visible</code>                                     |
| Tuples deleted | Total number of dead tuples vacuum operations deleted from tables of this database                                                                                                 | <code>tuples_deleted</code>                                        |
| Tuples left    | Total number of dead tuples vacuum operations left in tables of this database due to their visibility in transactions                                                              | <code>dead_tuples</code>                                           |
| %Eff           | Vacuum efficiency in terms of deleted tuples. This is the percentage of tuples deleted from tables of this database in all dead tuples to be deleted from tables of this database. | <code>tuples_deleted * 100 / (tuples_deleted + dead_tuples)</code> |
| WAL size       | Total amount of WAL bytes generated by vacuum operations performed on tables of this database                                                                                      | <code>wal_bytes</code>                                             |
| Read I/O time  | Time spent reading database blocks by vacuum operations performed on tables of this database                                                                                       | <code>blk_read_time</code>                                         |
| Write I/O time | Time spent writing database blocks by vacuum operations performed on tables of this database                                                                                       | <code>blk_write_time</code>                                        |
| %Total         | Vacuum I/O time spent as the percentage of whole cluster I/O time                                                                                                                  |                                                                    |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Column            | Description                                                                                           | Field/Calculation |
|-------------------|-------------------------------------------------------------------------------------------------------|-------------------|
| Total vacuum time | Total time of vacuuming tables of this database                                                       | total_time        |
| Delay vacuum time | Time spent sleeping in a vacuum delay point by vacuum operations performed on tables of this database | delay_time        |
| User CPU time     | User CPU time of vacuuming tables of this database                                                    | user_time         |
| System CPU time   | System CPU time of vacuuming tables of this database                                                  | system_time       |
| Interrupts        | Number of times vacuum operations performed on tables of this database were interrupted on any errors | interrupts        |

If the [pgpro\\_stats](#) extension supporting invalidation statistics was available during the report interval, the "Invalidation messages by database" report table provides per-database aggregated total invalidation message statistics. [Table G.8](#) lists columns of this report table.

**Table G.8. Invalidation messages by database**

| Column                     | Description                                                                                                                                                             | Field/Calculation                                    |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|
| Database                   | Database name                                                                                                                                                           |                                                      |
| Invalidation messages sent | Total number of invalidation messages sent by backends in this database. Statistics are provided for corresponding message types of <code>pgpro_stats_inval_msgs</code> | Fields of <code>pgpro_stats_totals.inval_msgs</code> |
| Cache resets               | Total number of shared cache resets                                                                                                                                     | <code>pgpro_stats_totals.cache_resets</code>         |

If the [pgpro\\_stats](#) extension was available during the report interval, the "Statement statistics by database" report table provides per-database aggregated total statistics for the `pgpro_stats_statements` view data. [Table G.9](#) lists columns of this report table. Times are provided in seconds.

**Table G.9. Statement statistics by database**

| Column     | Description                                                              | Field/Calculation                   |
|------------|--------------------------------------------------------------------------|-------------------------------------|
| Database   | Database name                                                            |                                     |
| Calls      | Number of times all statements in the database were executed             | calls                               |
| Plan Time  | Time spent planning all statements in the database                       | Sum of <code>total_plan_time</code> |
| Exec Time  | Time spent executing all statements in the database                      | Sum of <code>total_exec_time</code> |
| Read Time  | Time spent reading blocks by all statements in the database              | Sum of <code>blk_read_time</code>   |
| Write Time | Time spent writing blocks by all statements in the database              | Sum of <code>blk_write_time</code>  |
| Trg Time   | Time spent executing trigger functions by all statements in the database |                                     |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Column           | Description                                                                | Field/Calculation                            |
|------------------|----------------------------------------------------------------------------|----------------------------------------------|
| Shared Fetched   | Total number of shared blocks fetched by all statements in the database    | Sum of (shared_blks_read + shared_blks_hit ) |
| Local Fetched    | Total number of local blocks fetched by all statements in the database     | Sum of (local_blks_read + local_blks_hit )   |
| Shared Dirtied   | Total number of shared blocks dirtied by all statements in the database    | Sum of shared_blks_dirtied                   |
| Local Dirtied    | Total number of local blocks dirtied by all statements in the database     | Sum of local_blks_dirtied                    |
| Read Temp        | Total number of temporary blocks read by all statements in the database    | Sum of temp_blks_read                        |
| Write Temp       | Total number of temporary blocks written by all statements in the database | Sum of temp_blks_written                     |
| Read Local       | Total number of local blocks read by all statements in the database        | Sum of local_blks_read                       |
| Write Local      | Total number of local blocks written by all statements in the database     | Sum of local_blks_written                    |
| Statements       | Total number of captured statements                                        |                                              |
| WAL Size         | Total amount of WAL generated by all statements in the database            | Sum of wal_bytes                             |
| WAL buffers full | Number of times the WAL buffers became full                                |                                              |

The “Statement average min/max timings” report table contains per-database aggregated min/max timing statistics from the one of [pgpro\\_stats](#) or [pg\\_stat\\_statements](#) extensions that was available during the report interval, with the precedence of [pgpro\\_stats](#). This report is sensitive to the fastest and slowest planning and execution of every statement in a cluster. That is, you can see execution and planning stability in your database. [Table G.10](#) lists columns of this report table.

**Table G.10. Statement average min/max timings**

| Column                           | Description                                                                                                                                                                                  |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Database                         | Database name                                                                                                                                                                                |
| Min average planning time (ms)   | The average value of min_plan_time for all statements and all samples included in the report                                                                                                 |
| Max average planning time (ms)   | The average value of max_plan_time for all statements and all samples included in the report                                                                                                 |
| Delta% of average planning times | Difference between the mean max_plan_time and mean min_plan_time as the percentage of the mean min_plan_time . The less this difference, the more stable query planning in your database is. |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Column                            | Description                                                                                                                                                                                                                          |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Min average execution time (ms)   | The average value of <code>min_exec_time</code> for all statements and all samples included in the report                                                                                                                            |
| Max average execution time (ms)   | The average value of <code>max_exec_time</code> for all statements and all samples included in the report                                                                                                                            |
| Delta% of average execution times | Difference between the mean <code>max_exec_time</code> and mean <code>min_exec_time</code> as the percentage of the mean <code>min_exec_time</code> . The less this difference, the more stable query execution in your database is. |
| Statements                        | Total count of captured statements                                                                                                                                                                                                   |

If the JIT-related statistics was available in the statement statistics extension during the report interval, the “JIT statistics by database” report table provides per-database aggregated total statistics of JIT executions. [Table G.11](#) lists columns of this report table. Times are provided in seconds.

**Table G.11. JIT statistics by database**

| Column             | Description                                                                                    | Field/Calculation                          |
|--------------------|------------------------------------------------------------------------------------------------|--------------------------------------------|
| Database           | Database name                                                                                  |                                            |
| Calls              | Number of times all statements in the database were executed                                   | <code>calls</code>                         |
| Plan Time          | Time spent planning all statements in the database                                             | Sum of <code>total_plan_time</code>        |
| Exec Time          | Time spent executing all statements in the database                                            | Sum of <code>total_exec_time</code>        |
| Generation count   | Total number of functions JIT-compiled by the statements                                       | Sum of <code>jit_functions</code>          |
| Generation time    | Total time spent by the statements on generating JIT code                                      | Sum of <code>jit_generation_time</code>    |
| Inlining count     | Number of times functions have been inlined                                                    | Sum of <code>jit_inlining_count</code>     |
| Inlining time      | Total time spent by statements on inlining functions                                           | Sum of <code>jit_inlining_time</code>      |
| Optimization count | Number of times statements have been optimized                                                 | Sum of <code>jit_optimization_count</code> |
| Optimization time  | Total time spent by statements on optimizing                                                   | Sum of <code>jit_optimization_time</code>  |
| Emission count     | Number of times code has been emitted                                                          | Sum of <code>jit_emission_count</code>     |
| Emission time      | Total time spent by statements on emitting code                                                | Sum of <code>jit_emission_time</code>      |
| Deform count       | Number of tuple deform functions JIT-compiled by the statement of the database                 |                                            |
| Deform time        | Total time spent by the statements of the database on JIT-compiling the tuple deform functions |                                            |

The report table “Cluster statistics” provides data from the `pg_stat_bgwriter` and `pg_stat_checkpoint` views. The latter is available starting with Postgres Pro 17. [Table G.12](#) lists rows of this report table. Times are provided in seconds.

**Table G.12. Cluster statistics**

| Row                                    | Description                                                                                                                                                                                                | Field/Calculation                  |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|
| Scheduled checkpoints                  | Number of scheduled checkpoints that have been performed                                                                                                                                                   | <code>checkpoints_timed</code>     |
| Requested checkpoints                  | Number of requested checkpoints that have been performed                                                                                                                                                   | <code>checkpoints_req</code>       |
| Checkpoints done                       | Number of checkpoints that have been performed                                                                                                                                                             |                                    |
| Scheduled restartpoints                | Number of restartpoints scheduled due to timeout or after a failed attempt to perform a restartpoint                                                                                                       | <code>restartpoints_timed</code>   |
| Requested restartpoints                | Number of requested restartpoints if any                                                                                                                                                                   | <code>restartpoints_req</code>     |
| Restartpoints done                     | Number of restartpoints that have been performed if any                                                                                                                                                    | <code>restartpoints_done</code>    |
| Checkpoint write time (s)              | Total amount of time that has been spent in the portion of checkpoint and restartpoint processing where files are written to disk                                                                          | <code>checkpoint_write_time</code> |
| Checkpoint sync time (s)               | Total amount of time that has been spent in the portion of checkpoint and restartpoint processing where files are synchronized to disk                                                                     | <code>checkpoint_sync_time</code>  |
| Checkpoint buffers written             | Number of shared buffers written during checkpoints and restartpoints                                                                                                                                      | <code>buffers_checkpoint</code>    |
| SLRU buffers written by checkpoint     | Number of SLRU buffers written during checkpoints and restartpoints                                                                                                                                        |                                    |
| Background buffers written             | Number of buffers written by the background writer                                                                                                                                                         | <code>buffers_clean</code>         |
| Backend buffers written                | Number of buffers written directly by a backend. Will not be shown since Postgres Pro 17.                                                                                                                  | <code>buffers_backend</code>       |
| Backend fsync count                    | Number of times a backend had to execute its own <code>fsync</code> call (normally the background writer handles those even when the backend does its own write). Will not be shown since Postgres Pro 17. | <code>buffers_backend_fsync</code> |
| Bgwriter interrupts (too many buffers) | Number of times the background writer stopped a cleaning scan because it had written too many buffers                                                                                                      | <code>maxwritten_clean</code>      |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Row                         | Description                                           | Field/Calculation                                                         |
|-----------------------------|-------------------------------------------------------|---------------------------------------------------------------------------|
| Number of buffers allocated | Total number of buffers allocated                     | buffers_alloc                                                             |
| WAL generated               | Total amount of WAL generated                         | pg_current_wal_lsn() value increment                                      |
| Start LSN                   | Log sequence number at the start of a report interval | pg_current_wal_lsn() at the first sample of a report                      |
| End LSN                     | Log sequence number at the end of a report interval   | pg_current_wal_lsn() at the last sample of a report                       |
| WAL generated by vacuum     | Total amount of WAL generated by vacuum               | Based on the wal_bytes field of the pgpro_stats_vacuum_databases view.    |
| WAL segments archived       | Total number of archived WAL segments                 | Based on pg_stat_archiver.archived_count                                  |
| WAL segments archive failed | Total number of WAL segment archiver failures         | Based on pg_stat_archiver.failed_count .                                  |
| Archiver performance        | Average archiver process performance per second       | Based on the active_time field of the pgpro_stats_archiver view.          |
| Archive command performance | Average archive_command performance per second        | Based on the archive_command_time field of the pgpro_stats_archiver view. |

Table “WAL statistics” is available in the report for Postgres Pro databases starting with version 14. This table is based on the pg\_stat\_wal view of the [Statistics Collector](#). [Table G.13](#) lists columns of this report table. Times are provided in seconds.

**Table G.13. WAL statistics**

| Row                   | Description                                                                                                              | Field/Calculation           |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------|-----------------------------|
| WAL generated         | Total amount of WAL generated during the report interval                                                                 | wal_bytes                   |
| WAL per second        | Average amount of WAL generated per second during the report interval                                                    | wal_bytes / report_duration |
| WAL records           | Total number of WAL records generated during the report interval                                                         | wal_records                 |
| WAL FPI               | Total number of WAL full page images generated during the report interval                                                | wal_fpi                     |
| WAL buffers full      | Number of times WAL data was written to disk because WAL buffers became full during the report interval                  | wal_buffers_full            |
| WAL writes            | Number of times WAL buffers were written out to disk via XLogWrite request during the report interval                    | wal_write                   |
| WAL writes per second | Average number of times WAL buffers were written out to disk via XLogWrite request per second during the report interval | wal_write / report_duration |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Row                  | Description                                                                                                                                                                                                                                                                                                                                                                                                        | Field/Calculation                                   |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------|
| WAL sync             | Number of times WAL files were synced to disk via <code>issue_xlog_fsync</code> request during the report interval (if <code>fsync</code> is on and <code>wal_sync_method</code> is either <code>fdatasync</code> , <code>fsync</code> or <code>fsync_writethrough</code> , otherwise zero). See <a href="#">Section 29.5</a> for more information about the internal WAL function <code>issue_xlog_fsync</code> . | <code>wal_sync</code>                               |
| WAL syncs per second | Average number of times WAL files were synced to disk via <code>issue_xlog_fsync</code> request per second during the report interval                                                                                                                                                                                                                                                                              | <code>wal_sync / report_duration</code>             |
| WAL write time       | Total amount of time spent writing WAL buffers to disk via <code>XLogWrite</code> request during the report interval (if <code>track_wal_io_timing</code> is enabled, otherwise zero; for more details, see <a href="#">Section 19.9</a> ). This includes the sync time when <code>wal_sync_method</code> is either <code>open_datasync</code> or <code>open_sync</code> .                                         | <code>wal_write_time</code>                         |
| WAL write duty       | WAL write time as the percentage of the report interval duration                                                                                                                                                                                                                                                                                                                                                   | <code>wal_write_time * 100 / report_duration</code> |
| WAL sync time        | Total amount of time spent syncing WAL files to disk via <code>issue_xlog_fsync</code> request during the report interval (if <code>track_wal_io_timing</code> is enabled, <code>fsync</code> is on, and <code>wal_sync_method</code> is either <code>fdatasync</code> , <code>fsync</code> or <code>fsync_writethrough</code> , otherwise zero).                                                                  | <code>wal_sync_time</code>                          |
| WAL sync duty        | WAL sync time as the percentage of the report interval duration                                                                                                                                                                                                                                                                                                                                                    | <code>wal_sync_time * 100 / report_duration</code>  |

The report table “Tablespace statistics” provides information on the sizes and growth of tablespaces. [Table G.14](#) lists columns of this report table.

**Table G.14. Tablespace statistics**

| Column     | Description                                                           | Field/Calculation                                                   |
|------------|-----------------------------------------------------------------------|---------------------------------------------------------------------|
| Tablespace | Tablespace name                                                       | <code>pg_tablespace.spcname</code>                                  |
| Path       | Tablespace path                                                       | <code>pg_tablespace_location()</code>                               |
| Size       | Tablespace size at the time of the last sample in the report interval | <code>pg_tablespace_size()</code>                                   |
| Growth     | Tablespace growth during the report interval                          | <code>pg_tablespace_size()</code> increment between interval bounds |

If the [pgpro\\_stats](#) extension was available during the report interval, the report table “Wait statistics by database” shows the total wait time by wait event type and database. [Table G.15](#) lists columns of this report table.

**Table G.15. Wait statistics by database**

| Column          | Description                                                                                                            |
|-----------------|------------------------------------------------------------------------------------------------------------------------|
| Database        | Database name                                                                                                          |
| Wait event type | Type of event for which the backends were waiting. Asterisk means aggregation of all wait event types in the database. |
| Waited (s)      | Time spent waiting in events of <code>Wait event type</code> , in seconds                                              |
| %Total          | Percentage of wait time spent in the database events of <code>Wait event type</code> in all wait time for the cluster  |

If the [pgpro\\_stats](#) extension was available during the report interval, the report table “Top wait events” shows top wait events in the cluster by wait time. [Table G.16](#) lists columns of this report table.

**Table G.16. Top wait events**

| Column          | Description                                                                                              |
|-----------------|----------------------------------------------------------------------------------------------------------|
| Database        | Database name                                                                                            |
| Wait event type | The type of event for which the backends were waiting                                                    |
| Wait event      | Wait event name for which the backends were waiting                                                      |
| Waited          | Total wait time spent in <code>Wait event</code> of the database, in seconds                             |
| %Total          | Percentage of wait time spent in <code>Wait event</code> of the database in all wait time in the cluster |

### G.2.11.2. Load distribution

This section of a `pgpro_pwr` report is based on the `pgpro_stats_totals` view of the [pgpro\\_stats](#) extension if it was available during the report interval. Each table in this section provides data for the report interval on load distribution for a certain kind of objects for which aggregated statistics are collected, such as databases, applications, hosts, or users. Each table contains one row for each resource (for example, total time or shared blocks written), where load distribution is shown in graphics, as a stacked bar chart for top objects by load of this resource. If the bar chart area that corresponds to an object is too narrow to include captions, point that area to get a hint with the caption, value and percentage. The report tables “Load distribution among heavily loaded databases”, “Load distribution among heavily loaded applications”, “Load distribution among heavily loaded hosts” and “Load distribution among heavily loaded users” show load distribution for respective objects. [Table G.17](#) lists rows of these report tables.

**Table G.17. Load distribution**

| Row               | Description                                                   | Calculation                                                 |
|-------------------|---------------------------------------------------------------|-------------------------------------------------------------|
| Total time (sec.) | Total time spent in the planning and execution of statements  | <code>total_plan_time</code> + <code>total_exec_time</code> |
| Executed count    | Number of queries executed                                    | <code>queries_executed</code>                               |
| I/O time (sec.)   | Total time the statements spent reading or writing blocks (if | <code>blk_read_time</code> + <code>blk_write_time</code>    |

and Extensions Shipped  
as Individual Packages

| Row                           | Description                                                                      | Calculation                            |
|-------------------------------|----------------------------------------------------------------------------------|----------------------------------------|
|                               | <a href="#">track_io_timing</a> is enabled, otherwise zero)                      |                                        |
| Blocks fetched                | Total number of shared block cache hits and shared blocks read by the statements | shared_blks_hit + shared_blks_read     |
| Shared blocks read            | Total number of shared blocks read by the statements                             | shared_blks_read                       |
| Shared blocks dirtied         | Total number of shared blocks dirtied by the statements                          | shared_blks_dirtied                    |
| Shared blocks written         | Total number of shared blocks written by the statements                          | shared_blks_written                    |
| WAL generated                 | Total amount of WAL generated by the statements                                  | wal_bytes                              |
| Temp and Local blocks written | Total number of temporary and local blocks written by the statements             | temp_blks_written + local_blks_written |
| Temp and Local blocks read    | Total number of temp and local blocks read by the statements                     | temp_blks_read + local_blks_read       |
| Invalidation messages sent    | Total number of all invalidation messages sent by backends in this database      | (pgpro_stats_totals .invalid_msgs).all |
| Cache resets                  | Total number of shared cache resets                                              | pgpro_stats_totals .cache_resets       |

### G.2.11.3. Session states observed by subsamples

This section of a pgpro\_pwr report provides information about session states captured by subsamples during the report interval.

Tables of this report section are described below.

The report subsection “Chart with session state” visualizes session states captured by subsamples. It is the timeline chart showing captured session states in backends and transactions. Every state contains a popup with session state attributes. Click on a state to see this state in the table of session states.

The report table “Session state statistics by database” shows the aggregated data on session states. Only session states captured in subsamples are counted. [Table G.18](#) lists columns of this report table.

**Table G.18. Session state statistics by database**

| Column                   | Description                                                                 |
|--------------------------|-----------------------------------------------------------------------------|
| Database                 | Database name                                                               |
| Summary Active           | Overall time of active states captured in subsamples                        |
| Summary Idle in xact     | Overall time of idle in transaction states captured in subsamples           |
| Summary Idle in xact (A) | Overall time of idle in transaction (aborted) states captured in subsamples |
| Maximal Active           | Time of the longest active state captured in subsamples                     |
| Maximal Idle in xact     | Time of the longest idle in transaction state captured in subsamples        |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Column                   | Description                                                                    |
|--------------------------|--------------------------------------------------------------------------------|
| Maximal Idle in xact (A) | Time of the longest idle in transaction (aborted) state captured in subsamples |
| Maximal xact age         | Maximal transaction age detected in subsamples                                 |

The report table “Top 'idle in transaction' session states by duration” shows top `pgpro_pwr.max` longest idle in transaction states that were last observed in the [pg\\_stat\\_activity](#) view for each session. [Table G.19](#) lists columns of this report table.

**Table G.19. Top 'idle in transaction' session states by duration**

| Column         | Description                 | Field/Calculation                             |
|----------------|-----------------------------|-----------------------------------------------|
| Database       | Database name               | <code>datname</code>                          |
| User           | User name                   | <code>username</code>                         |
| App            | Application name            | <code>application_name</code>                 |
| Pid            | Process ID                  | <code>pid</code>                              |
| Xact start     | Transaction start timestamp | <code>xact_start</code>                       |
| State change   | State change timestamp      | <code>state_change</code>                     |
| State duration | State duration              | <code>clock_timestamp() - state_change</code> |

The report table “Top 'active' session states by duration” shows top `pgpro_pwr.max` longest active states that were last observed in the [pg\\_stat\\_activity](#) view for each session. [Table G.20](#) lists columns of this report table.

**Table G.20. Top 'active' session states by duration**

| Column         | Description                 | Field/Calculation                             |
|----------------|-----------------------------|-----------------------------------------------|
| Database       | Database name               | <code>datname</code>                          |
| User           | User name                   | <code>username</code>                         |
| App            | Application name            | <code>application_name</code>                 |
| Pid            | Process ID                  | <code>pid</code>                              |
| Xact start     | Transaction start timestamp | <code>xact_start</code>                       |
| State change   | State change timestamp      | <code>state_change</code>                     |
| State duration | State duration              | <code>clock_timestamp() - state_change</code> |

The report table “Top states by transaction age” shows top session states by transaction age that were last observed in the [pg\\_stat\\_activity](#) view for each session. [Table G.21](#) lists columns of this report table.

**Table G.21. Top states by transaction age**

| Column        | Description                 | Field/Calculation                           |
|---------------|-----------------------------|---------------------------------------------|
| Database      | Database name               | <code>datname</code>                        |
| User          | User name                   | <code>username</code>                       |
| App           | Application name            | <code>application_name</code>               |
| Pid           | Process ID                  | <code>pid</code>                            |
| Xact start    | Transaction start timestamp | <code>xact_start</code>                     |
| Xact duration | Transaction duration        | <code>clock_timestamp() - xact_start</code> |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Column         | Description                               | Field/Calculation                             |
|----------------|-------------------------------------------|-----------------------------------------------|
| Age            | Transaction age                           | <code>age ( backend_xmin )</code>             |
| State          | Session state at the maximum age detected |                                               |
| State change   | State change timestamp                    | <code>state_change</code>                     |
| State duration | State duration                            | <code>clock_timestamp() - state_change</code> |

The report table “Top states by transaction duration” shows top longest session states that were last observed in the [pg\\_stat\\_activity](#) view for each session. [Table G.22](#) lists columns of this report table.

**Table G.22. Top states by transaction duration**

| Column         | Description                               | Field/Calculation                             |
|----------------|-------------------------------------------|-----------------------------------------------|
| Database       | Database name                             | <code>datname</code>                          |
| User           | User name                                 | <code>username</code>                         |
| App            | Application name                          | <code>application_name</code>                 |
| Pid            | Process ID                                | <code>pid</code>                              |
| Xact start     | Transaction start timestamp               | <code>xact_start</code>                       |
| Xact duration  | Transaction duration                      | <code>clock_timestamp() - xact_start</code>   |
| Age            | Transaction age                           | <code>age ( backend_xmin )</code>             |
| State          | Session state at the maximum age detected |                                               |
| State change   | State change timestamp                    | <code>state_change</code>                     |
| State duration | State duration                            | <code>clock_timestamp() - state_change</code> |

#### G.2.11.4. SQL query statistics

This section of a `pgpro_pwr` report provides data for the report interval on top statements by several important statistics. The data is mainly captured from views of the one of [pgpro\\_stats](#) and [pg\\_stat\\_statements](#) extensions that was available during the report interval, with the precedence of `pgpro_stats`. Each statement can be highlighted in all SQL-related sections with a single mouse click on it. This click will also show a query text preview just under the query statistics row. The query text preview can be hidden with a second click on a query.

Tables of this report section are described below.

The report table “Top SQL by elapsed time” shows top statements by the sum of `total_plan_time` and `total_exec_time` fields of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table G.23](#) lists columns of this report table. Times are provided in seconds.

**Table G.23. Top SQL by elapsed time**

| Column   | Description                                                                                                                                                                                                                         | Field/Calculation |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Query ID | Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements). |                   |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Column             | Description                                                                                                  | Field/Calculation                                                                   |
|--------------------|--------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| Plan ID            | Internal hash code, computed from the tree of the statement plan                                             | planid                                                                              |
| Database           | Database name for the statement                                                                              | Derived from dbid                                                                   |
| User               | Name of the user executing the statement                                                                     | Derived from userid                                                                 |
| %Total             | Percentage of elapsed time of this statement plan in the total elapsed time of all statements in the cluster |                                                                                     |
| Elapsed Time (s)   | Total time spent in planning and execution of the statement plan                                             | total_plan_time + total_exec_time                                                   |
| Plan Time (s)      | Total time spent in planning of the statement                                                                | total_plan_time                                                                     |
| Exec Time (s)      | Total time spent in execution of the statement plan                                                          | total_exec_time                                                                     |
| JIT Time (s)       | Total time spent by JIT executing this statement plan, in seconds                                            | jit_generation_time + jit_inlining_time + jit_optimization_time + jit_emission_time |
| Read I/O time (s)  | Total time the statement spent reading blocks                                                                | blk_read_time                                                                       |
| Write I/O time (s) | Total time the statement spent writing blocks                                                                | blk_write_time                                                                      |
| Usr CPU time (s)   | Time spent on CPU in the user space, in seconds                                                              | rusage.user_time                                                                    |
| Sys CPU time (s)   | Time spent on CPU in the system space, in seconds                                                            | rusage.system_time                                                                  |
| Plans              | Number of times the statement was planned                                                                    | plans                                                                               |
| Executions         | Number of executions of the statement plan                                                                   | calls                                                                               |

| Plan ID          | Internal hash code, computed from the tree of the statement plan                                                                                                                                                                    | planid                           |
| Database         | Database name for the statement                                                                                                                                                                                                     | Derived from <code>dbid</code>   |
| User             | Name of the user executing the statement                                                                                                                                                                                            | Derived from <code>userid</code> |
| WAL              | Total amount of WAL bytes generated by the statement plan                                                                                                                                                                           | wal_bytes                        |
| %Total           | Percentage of WAL bytes generated by the statement plan in total WAL generated in the cluster                                                                                                                                       |                                  |
| WAL buffers full | Number of times the WAL buffers became full                                                                                                                                                                                         |                                  |
| Dirtied          | Number of shared buffers dirtied while executing this statement plan                                                                                                                                                                | shared_blks_dirtied              |
| WAL FPI          | Total number of WAL full page images generated by the statement plan                                                                                                                                                                | wal_fpi                          |
| WAL records      | Total number of WAL records generated by the statement plan                                                                                                                                                                         | wal_records                      |
| %Cvr             | Coverage: duration of statement statistics collection as the percentage of the report duration                                                                                                                                      |                                  |

The report table “Top SQL by temp usage” shows top statements by temporary I/O, which is calculated as the sum of `temp_blks_read`, `temp_blks_written`, `local_blks_read` and `local_blks_written` fields. [Table G.34](#) lists columns of this report table.

**Table G.34. Top SQL by temp usage**

| Column             | Description                                                                                                                                                                                                                         | Field/Calculation                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| Query ID           | Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements). |                                                             |
| Plan ID            | Internal hash code, computed from the tree of the statement plan                                                                                                                                                                    | <code>planid</code>                                         |
| Database           | Database name for the statement                                                                                                                                                                                                     | Derived from <code>dbid</code>                              |
| User               | Name of the user executing the statement                                                                                                                                                                                            | Derived from <code>userid</code>                            |
| Local fetched      | Number of local blocks retrieved                                                                                                                                                                                                    | <code>local_blks_hit</code> + <code>local_blks_read</code>  |
| Hits(%)            | Percentage of local blocks got from buffers in all local blocks got                                                                                                                                                                 |                                                             |
| Write Local (blk)  | Number of blocks written by this statement plan that are used in temporary tables                                                                                                                                                   | <code>local_blks_written</code>                             |
| Write Local %Total | Percentage of <code>local_blks_written</code> of this statement plan in the total of <code>local_blks_written</code> for all statements in the cluster                                                                              |                                                             |
| Read Local (blk)   | Number of blocks read by this statement plan that are used in temporary tables                                                                                                                                                      | <code>local_blks_read</code>                                |
| Read Local %Total  | Percentage of <code>local_blks_read</code> of this statement plan in the total of <code>local_blks_read</code> for all statements in the cluster                                                                                    |                                                             |
| Write Temp (blk)   | Number of temporary blocks written by this statement plan                                                                                                                                                                           | <code>temp_blks_written</code>                              |
| Write Temp %Total  | Percentage of <code>temp_blks_written</code> of this statement plan in the total of <code>temp_blks_written</code> for all statements in the cluster                                                                                |                                                             |
| Read Temp (blk)    | Number of temporary blocks read by this statement plan                                                                                                                                                                              | <code>temp_blks_read</code>                                 |

|-----------------|-----------------------------------------------------------------------------------------------------------------------------|---------------------|
| Plan ID         | Internal hash code, computed from the tree of the statement plan                                                            | planid              |
| Database        | Database name for the statement                                                                                             | Derived from dbid   |
| User            | Name of the user executing the statement                                                                                    | Derived from userid |
| Plan User (s)   | User CPU time elapsed during planning, in seconds                                                                           | plan_user_time      |
| Exec User (s)   | User CPU time elapsed during execution, in seconds                                                                          | exec_user_time      |
| User %Total     | Percentage of <code>plan_user_time</code> + <code>exec_user_time</code> in the total user CPU time for all statements       |                     |
| Plan System (s) | System CPU time elapsed during planning, in seconds                                                                         | plan_system_time    |
| Exec System (s) | System CPU time elapsed during execution, in seconds                                                                        | exec_system_time    |
| System %Total   | Percentage of <code>plan_system_time</code> + <code>exec_system_time</code> in the total system CPU time for all statements |                     |

The report table “Top SQL by reads/writes done by filesystem layer” shows top statements by the sum of reads and writes fields of `pg_stat_kcache`. [Table G.37](#) lists columns of this report table.

**Table G.37. Top SQL by reads/writes done by filesystem layer**

| Column            | Description                                                                                                                                                                                                                         | Field/Calculation   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| Query ID          | Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements). |                     |
| Plan ID           | Internal hash code, computed from the tree of the statement plan                                                                                                                                                                    | planid              |
| Database          | Database name for the statement                                                                                                                                                                                                     | Derived from dbid   |
| User              | Name of the user executing the statement                                                                                                                                                                                            | Derived from userid |
| Plan Read Bytes   | Bytes read during planning                                                                                                                                                                                                          | plan_reads          |
| Exec Read Bytes   | Bytes read during execution                                                                                                                                                                                                         | exec_reads          |
| Read Bytes %Total | Percentage of <code>plan_reads</code> + <code>exec_reads</code> in the total number of bytes read by the filesystem layer for all statements                                                                                        |                     |
| Plan Writes       | Bytes written during planning                                                                                                                                                                                                       | plan_writes         |
| Exec Writes       | Bytes written during execution                                                                                                                                                                                                      | exec_writes         |

### G.2.11.5. SQL query wait statistics

If the `pgpro_stats` extension was available during the report interval, this section of the report will contain a table that is split into sections, each showing top statements by overall wait time or by wait time for a certain `wait event type`. Table sections related to specific wait events follow in the descending order of the total wait time in wait events of this type. [Table G.38](#) lists columns of this report table. Times are provided in seconds.

**Table G.38. SQL query wait statistics**

| Column   | Description                                                                                                                                                                                                                         | Field/Calculation                |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------|
| Query ID | Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements). |                                  |
| Plan ID  | Hash of the statement plan                                                                                                                                                                                                          | <code>planid</code>              |
| Database | Database name for the statement                                                                                                                                                                                                     | Derived from <code>dbid</code>   |
| User     | Name of the user executing the statement                                                                                                                                                                                            | Derived from <code>userid</code> |
| Waited   | Total wait time for all wait events of this statement plan                                                                                                                                                                          |                                  |
| %Total   | Percentage of the total wait time of this statement plan in all the wait time in the cluster                                                                                                                                        |                                  |
| Details  | Waits of this statement plan by wait types                                                                                                                                                                                          |                                  |

If the JIT-related statistics was available in the statement statistics extension during the report interval, the report table “Top SQL by JIT elapsed time” shows top statements by the sum of `jit_*_time` fields of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table G.39](#) lists columns of this report table. Times are provided in seconds.

**Table G.39. Top SQL by JIT elapsed time**

| Column   | Description                                                                                                                                                                                                                         | Field/Calculation   |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| Query ID | Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements). |                     |
| Plan ID  | Internal hash code, computed from the tree of the statement plan                                                                                                                                                                    | <code>planid</code> |

| Exec Time (s)      | Total time spent in execution of the statement plan                                            | <code>total_exec_time</code>                                                                     |
| Read I/O time (s)  | Total time the statement spent reading blocks                                                  | <code>blk_read_time</code>                                                                       |
| Write I/O time (s) | Total time the statement spent writing blocks                                                  | <code>blk_write_time</code>                                                                      |
| %Cvr               | Coverage: duration of statement statistics collection as the percentage of the report duration |                                                                                                  |

#### G.2.11.6. Top SQL by parallel workers usage

The “Top SQL by parallel workers usage” section of the report shows top statements by planned and launched parallel workers, that is, by the sum of `parallel_workers_to_launch` and `parallel_workers_launched` fields of the `pg_stat_statements` view. Some of these statistics are only available starting with Postgres Pro 18. [Table G.40](#) lists columns of this report table. Times are provided in seconds.

**Table G.40. Top SQL by parallel workers usage**

| Column                    | Description                                                                                                                                                                                                                         | Field/Calculation                                            |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|
| Query ID                  | Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements). |                                                              |
| Database                  | Database name for the statement                                                                                                                                                                                                     | Derived from <code>dbid</code>                               |
| User                      | Name of the user executing the statement                                                                                                                                                                                            | Derived from <code>userid</code>                             |
| Planned Parallel workers  | Number of parallel workers planned to be launched                                                                                                                                                                                   |                                                              |
| Launched Parallel workers | Number of parallel workers actually launched                                                                                                                                                                                        |                                                              |
| Exec (s)                  | System CPU time elapsed during execution                                                                                                                                                                                            | <code>exec_system_time</code> or <code>system_time</code>    |
| Blks fetched              | Number of fetched blocks                                                                                                                                                                                                            | <code>shared_blks_hit</code> + <code>shared_blks_read</code> |
| Shr Reads                 | Total number of shared blocks read by the statement plan                                                                                                                                                                            | <code>shared_blks_read</code>                                |
| Loc Reads                 | Total number of local blocks read by the statement plan                                                                                                                                                                             | <code>local_blks_read</code>                                 |
| Tmp Reads                 | Total number of temporary blocks read by the statement plan                                                                                                                                                                         | <code>temp_blks_read</code>                                  |
| Read I/O time (s)         | Time spent reading blocks                                                                                                                                                                                                           | <code>blk_read_time</code>                                   |
| Write I/O time (s)        | Time spent writing blocks                                                                                                                                                                                                           | <code>blk_write_time</code>                                  |

### G.2.11.7. Complete list of SQL texts

The “Complete list of SQL texts” section of the report contains a table that provides query and plan texts for all statements mentioned in the report. Use an appropriate `Query ID/Plan ID` link in any statistics table to see the corresponding query/plan text. [Table G.41](#) lists columns of this report table.

**Table G.41. Complete list of SQL texts**

| Column          | Description                                        |
|-----------------|----------------------------------------------------|
| ID              | Hex representation of the query or plan identifier |
| Query/Plan Text | Text of the query or statement plan                |

### G.2.11.8. Schema object statistics

Tables in this section of the report show top database objects by statistics from the Postgres Pro's [Statistics Collector](#) views. Report tables that contain data for tables and indexes provide a preview of storage parameters. You can click on a row to see storage parameters of the object right under the row.

The report table “Top tables by estimated sequentially scanned volume” shows top tables by estimated volume read by sequential scans. This can help you find database tables that possibly lack some index. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. The data is based on the `pg_stat_all_tables` view. [Table G.42](#) lists columns of this report table.

**Table G.42. Top tables by estimated sequentially scanned volume**

| Column     | Description                                       | Field/Calculation                       |
|------------|---------------------------------------------------|-----------------------------------------|
| DB         | Database name for the table                       |                                         |
| Tablespace | Name of the tablespace where the table is located |                                         |
| Schema     | Schema name for the table                         |                                         |
| Table      | Table name                                        |                                         |
| ~SeqBytes  | Estimated volume read by sequential scans         | Sum of (pg_relation_size() * seq_scan ) |
| SeqScan    | Number of sequential scans performed on the table | seq_scan                                |
| IxScan     | Number of index scans initiated on the table      | idx_scan                                |
| IxFet      | Number of live rows fetched by index scans        | idx_tup_fetch                           |
| Ins        | Number of rows inserted                           | n_tup_ins                               |
| Upd        | Number of rows updated                            | n_tup_upd                               |
| Del        | Number of rows deleted                            | n_tup_del                               |
| Upd (HOT)  | Number of rows HOT updated                        | n_tup_hot_upd                           |

In the report table “Top tables by blocks fetched”, blocks fetched include blocks being processed from disk (read) and from shared buffers (hit). This report table shows top database tables by the sum of blocks fetched for the table's heap, indexes, TOAST table (if any) and TOAST table index (if any). This can help you focus on tables with excessive processing of blocks. The data is based on the [pg\\_statio\\_all\\_tables](#) view. [Table G.43](#) lists columns of this report table.

**Table G.43. Top tables by blocks fetched**

| Column            | Description                                                                                   | Field/Calculation                |
|-------------------|-----------------------------------------------------------------------------------------------|----------------------------------|
| DB                | Database name for the table                                                                   |                                  |
| Tablespace        | Name of the tablespace where the table is located                                             |                                  |
| Schema            | Schema name for the table                                                                     |                                  |
| Table             | Table name                                                                                    |                                  |
| Heap Blks         | Number of blocks fetched for the table's heap                                                 | heap_blks_read + heap_blks_hit   |
| Heap Blks %Total  | Percentage of blocks fetched for the table's heap in all blocks fetched in the cluster        |                                  |
| Ix Blks           | Number of blocks fetched for table's indexes                                                  | idx_blks_read + idx_blks_hit     |
| Ix Blks %Total    | Percentage of blocks fetched for table's indexes in all blocks fetched in the cluster         |                                  |
| TOAST Blks        | Number of blocks fetched for the table's TOAST table                                          | toast_blks_read + toast_blks_hit |
| TOAST Blks %Total | Percentage of blocks fetched for the table's TOAST table in all blocks fetched in the cluster |                                  |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Column               | Description                                                                                   | Field/Calculation                           |
|----------------------|-----------------------------------------------------------------------------------------------|---------------------------------------------|
| TOAST-Ix Blks        | Number of blocks fetched for the table's TOAST index                                          | <code>tidx_blks_read + tidx_blks_hit</code> |
| TOAST-Ix Blks %Total | Percentage of blocks fetched for the table's TOAST index in all blocks fetched in the cluster |                                             |

The report table “Top tables by blocks read” shows top database tables by the number of blocks read for the table's heap, indexes, TOAST table (if any) and TOAST table index (if any). This can help you focus on tables with excessive block readings. The data is based on the [pg\\_statio\\_all\\_tables](#) view. [Table G.44](#) lists columns of this report table.

**Table G.44. Top tables by blocks read**

| Column               | Description                                                                                                                                                  | Field/Calculation            |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|
| DB                   | Database name for the table                                                                                                                                  |                              |
| Tablespace           | Name of the tablespace where the table is located                                                                                                            |                              |
| Schema               | Schema name for the table                                                                                                                                    |                              |
| Table                | Table name                                                                                                                                                   |                              |
| Heap Blks            | Number of blocks read for the table's heap                                                                                                                   | <code>heap_blks_read</code>  |
| Heap Blks %Total     | Percentage of blocks read from the table's heap in all blocks read in the cluster                                                                            |                              |
| Ix Blks              | Number of blocks read from table's indexes                                                                                                                   | <code>idx_blks_read</code>   |
| Ix Blks %Total       | Percentage of blocks read from table's indexes in all blocks read in the cluster                                                                             |                              |
| TOAST Blks           | Number of blocks read from the table's TOAST table                                                                                                           | <code>toast_blks_read</code> |
| TOAST Blks %Total    | Percentage of blocks read from the table's TOAST table in all blocks read in the cluster                                                                     |                              |
| TOAST-Ix Blks        | Number of blocks read from the table's TOAST index                                                                                                           | <code>tidx_blks_read</code>  |
| TOAST-Ix Blks %Total | Percentage of blocks read from the table's TOAST index in all blocks read in the cluster                                                                     |                              |
| Hit (%)              | Percentage of table, index, TOAST and TOAST index blocks got from buffers for this table in all blocks got for this table from either file system or buffers |                              |

The report table “Top DML tables” shows top tables by the number of DML-affected rows, i.e., by the sum of `n_tup_ins`, `n_tup_upd` and `n_tup_del` (including TOAST tables). The data is based on the [pg\\_stat\\_all\\_tables](#) view. [Table G.45](#) lists columns of this report table.

**Table G.45. Top DML tables**

| Column     | Description                                       | Field/Calculation |
|------------|---------------------------------------------------|-------------------|
| DB         | Database name for the table                       |                   |
| Tablespace | Name of the tablespace where the table is located |                   |
| Schema     | Schema name for the table                         |                   |
| Table      | Table name                                        |                   |
| Ins        | Number of rows inserted                           | n_tup_ins         |
| Upd        | Number of rows updated, including HOT             | n_tup_upd         |
| Del        | Number of rows deleted                            | n_tup_del         |
| Upd (HOT)  | Number of rows HOT updated                        | n_tup_hot_upd     |
| SeqScan    | Number of sequential scans performed on the table | seq_scan          |
| SeqFet     | Number of live rows fetched by sequential scans   | seq_tup_read      |
| IxScan     | Number of index scans initiated on this table     | idx_scan          |
| IxFet      | Number of live rows fetched by index scans        | idx_tup_fetch     |

The report table “Top tables by updated/deleted tuples” shows top tables by tuples modified by UPDATE/DELETE operations, i.e., by the sum of `n_tup_upd` and `n_tup_del` (including TOAST tables). The data is based on the `pg_stat_all_tables` view. Table G.46 lists columns of this report table.

**Table G.46. Top tables by updated/deleted tuples**

| Column                    | Description                                                                                    | Field/Calculation |
|---------------------------|------------------------------------------------------------------------------------------------|-------------------|
| DB                        | Database name for the table                                                                    |                   |
| Tablespace                | Name of the tablespace where the table is located                                              |                   |
| Schema                    | Schema name for the table                                                                      |                   |
| Table                     | Table name                                                                                     |                   |
| Upd                       | Number of rows updated, including HOT                                                          | n_tup_upd         |
| Upd (HOT)                 | Number of rows HOT updated                                                                     | n_tup_hot_upd     |
| Del                       | Number of rows deleted                                                                         | n_tup_del         |
| Vacuum Vacuum count       | Number of times this table has been manually vacuumed (not counting <code>VACUUM FULL</code> ) | vacuum_count      |
| Autovacuum Vacuum count   | Number of times this table has been vacuumed by the autovacuum daemon                          | autovacuum_count  |
| Analyze Analyze count     | Number of times this table was manually analyzed                                               | analyze_count     |
| AutoAnalyze Analyze count | Number of times this table was analyzed by the autovacuum daemon                               | autoanalyze_count |

The report table “Top tables by removed all-visible marks” shows top tables by the number of times that the all-visible mark was removed from the visibility map by any backend. This report section is only shown when corresponding statistics are available. [Table G.47](#) lists columns of this report table.

**Table G.47. Top tables by removed all-visible marks**

| Column                    | Description                                                                                                           | Field/Calculation                                                                                     |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|

and Extensions Shipped  
as Individual Packages

| Column     | Description                                                                                    | Field/Calculation             |
|------------|------------------------------------------------------------------------------------------------|-------------------------------|
| Vacuum     | Number of times this table has been manually vacuumed (not counting <code>VACUUM FULL</code> ) | <code>vacuum_count</code>     |
| AutoVacuum | Number of times this table has been vacuumed by the autovacuum daemon                          | <code>autovacuum_count</code> |

The report table “Top tables by new-page updated tuples” shows top tables by the number of rows updated where the successor version goes onto a *new* heap page, leaving behind an original version with a `t_ctid` field that points to a different heap page. These are always non-HOT updates. [Table G.49](#) lists columns of this report table.

**Table G.49. Top tables by new-page updated tuples**

| Column     | Description                                                               |
|------------|---------------------------------------------------------------------------|
| DB         | Database name for the table                                               |
| Tablespace | Name of the tablespace where the table is located                         |
| Schema     | Schema name for the table                                                 |
| Table      | Table name                                                                |
| NP Upd     | Number of rows updated to a new heap page                                 |
| %Upd       | Number of new-page updated rows as the percentage of all rows updated     |
| Upd        | Number of rows updated, including HOT                                     |
| Upd (HOT)  | Number of rows HOT updated (i.e., with no separate index update required) |

The report table “Top growing tables” shows top tables by growth. The data is based on the `pg_stat_all_tables` view. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. [Table G.50](#) lists columns of this report table.

**Table G.50. Top growing tables**

| Column     | Description                                                      | Field/Calculation                                                   |

| Ins        | Number of rows inserted                                          | <code>n_tup_ins</code>                                              |
| Upd        | Number of rows updated, including HOT                            | <code>n_tup_upd</code>                                              |
| Del        | Number of rows deleted                                           | <code>n_tup_del</code>                                              |
| Upd (HOT)  | Number of rows HOT updated                                       | <code>n_tup_hot_upd</code>                                          |

In the report table “Top indexes by blocks fetched”, blocks fetched include index blocks processed from disk (read) and from shared buffers (hit). The data is based on the `pg_statio_all_indexes` view. [Table G.51](#) lists columns of this report table.

**Table G.51. Top indexes by blocks fetched**

| Column     | Description                                                                      | Field/Calculation            |
|------------|----------------------------------------------------------------------------------|------------------------------|
| DB         | Database name for the index                                                      |                              |
| Tablespace | Name of the tablespace where the index is located                                |                              |
| Schema     | Schema name for the underlying table                                             |                              |
| Table      | Underlying table name                                                            |                              |
| Index      | Index name                                                                       |                              |
| Scans      | Number of index scans initiated on this index                                    | idx_scan                     |
| Blks       | Number of blocks fetched for this index                                          | idx_blks_read + idx_blks_hit |
| %Total     | Percentage of blocks fetched for this index in all blocks fetched in the cluster |                              |

The report table “Top indexes by blocks read” is also based on the [pg\\_statio\\_all\\_indexes](#) and [pg\\_stat\\_all\\_indexes](#) views. [Table G.52](#) lists columns of this report table.

**Table G.52. Top indexes by blocks read**

| Column     | Description                                                                           | Field/Calculation |
|------------|---------------------------------------------------------------------------------------|-------------------|
| DB         | Database name for the index                                                           |                   |
| Tablespace | Name of the tablespace where the index is located                                     |                   |
| Schema     | Schema name for the underlying table                                                  |                   |
| Table      | Underlying table name                                                                 |                   |
| Index      | Index name                                                                            |                   |
| Scans      | Number of index scans initiated on this index                                         | idx_scan          |
| Blk Reads  | Number of disk blocks read from this index                                            | idx_blks_read     |
| %Total     | Percentage of disk blocks read from this index in all disk blocks read in the cluster |                   |
| Hits(%)    | Percentage of index blocks got from buffers in all index blocks got for this index    |                   |

The report table “Top growing indexes” shows top indexes by growth. The table uses data from the [pg\\_stat\\_all\\_tables](#) and [pg\\_stat\\_all\\_indexes](#) views. When there are no relation sizes collected with [pg\\_relation\\_size\(\)](#), relation-size estimates are based on the [pg\\_class.relpages](#) field. Since such values are less accurate, they are shown in square brackets. [Table G.53](#) lists columns of this report table.

**Table G.53. Top growing indexes**

| Column | Description                 | Field/Calculation |
|--------|-----------------------------|-------------------|
| DB     | Database name for the index |                   |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Column       | Description                                                      | Field/Calculation                      |
|--------------|------------------------------------------------------------------|----------------------------------------|
| Tablespace   | Name of the tablespace where the index is located                |                                        |
| Schema       | Schema name for the underlying table                             |                                        |
| Table        | Underlying table name                                            |                                        |
| Index        | Index name                                                       |                                        |
| Index Size   | Index size at the time of the last sample in the report interval | <code>pg_relation_size()</code>        |
| Index Growth | Index growth during the report interval                          |                                        |
| Table Ins    | Number of rows inserted into the underlying table                | <code>n_tup_ins</code>                 |
| Table Upd    | Number of rows updated in the underlying table, without HOT      | <code>n_tup_upd - n_tup_hot_upd</code> |
| Table Del    | Number of rows deleted from the underlying table                 | <code>n_tup_del</code>                 |

The report table “Unused indexes” shows top non-scanned indexes (during the report interval) by DML operations on underlying tables that caused index support. Constraint indexes are not counted. The table uses data from the `pg_stat_all_tables` view. Table G.54 lists columns of this report table.

**Table G.54. Unused indexes**

| Column       | Description                                                      | Field/Calculation                      |
|--------------|------------------------------------------------------------------|----------------------------------------|
| DB           | Database name for the index                                      |                                        |
| Tablespace   | Name of the tablespace where the index is located                |                                        |
| Schema       | Schema name for the underlying table                             |                                        |
| Table        | Underlying table name                                            |                                        |
| Index        | Index name                                                       |                                        |
| Index Size   | Index size at the time of the last sample in the report interval | <code>pg_relation_size()</code>        |
| Index Growth | Index growth during the report interval                          |                                        |
| Table Ins    | Number of rows inserted into the underlying table                | <code>n_tup_ins</code>                 |
| Table Upd    | Number of rows updated in the underlying table, without HOT      | <code>n_tup_upd - n_tup_hot_upd</code> |
| Table Del    | Number of rows deleted from the underlying table                 | <code>n_tup_del</code>                 |

### G.2.11.9. User function statistics

Tables in this section of the report show top functions in the cluster by statistics from the `pg_stat_user_functions` view. Times in the tables are provided in seconds.

The report table “Top functions by total time” shows top functions by the total time elapsed. The report table “Top functions by executions” shows top functions by the number of executions. The report table

“Top trigger functions by total time” shows top trigger functions by the total time elapsed. [Table G.55](#) lists columns of these report tables.

**Table G.55. User function statistics**

| Column             | Description                                                                          | Field/Calculation              |
|--------------------|--------------------------------------------------------------------------------------|--------------------------------|
| DB                 | Database name for the function                                                       |                                |
| Schema             | Schema name for the function                                                         |                                |
| Function           | Function name                                                                        |                                |
| Executions         | Number of times this function has been called                                        | <code>calls</code>             |
| Total Time (s)     | Total time spent in this function and all other functions called by it               | <code>total_time</code>        |
| Self Time (s)      | Total time spent in this function itself, not including other functions called by it | <code>self_time</code>         |
| Mean Time (s)      | Mean time of a single function execution                                             | <code>total_time /calls</code> |
| Mean self Time (s) | Mean self time of a single function execution                                        | <code>self_time /calls</code>  |

#### G.2.11.10. Vacuum-related statistics

The report table “Top tables by vacuum time spent” is available if [pgpro\\_stats](#) can provide extended vacuum statistics. This table shows top tables by total time spent vacuuming them. The data is based on the `pgpro_stats_vacuum_tables` view. [Table G.56](#) lists columns of this report table.

**Table G.56. Top tables by vacuum time spent**

| Column                 | Description                                                                                                                  | Field/Calculation          |
|------------------------|------------------------------------------------------------------------------------------------------------------------------|----------------------------|
| DB                     | Database name for the table                                                                                                  |                            |
| Tablespace             | Name of the tablespace where the table is located                                                                            |                            |
| Schema                 | Schema name for the table                                                                                                    |                            |
| Table                  | Table name                                                                                                                   |                            |
| Total Vacuum time      | Total time of vacuuming this table                                                                                           | <code>total_time</code>    |
| Delay Vacuum time      | Time spent sleeping in a vacuum delay point by vacuum operations performed on this table                                     | <code>delay_time</code>    |
| Vacuum Vacuum time     | Total time this table was manually vacuumed. This includes the time spent sleeping due to cost-based delays.                 |                            |
| Autovacuum Vacuum time | Total time this table was vacuumed by the autovacuum daemon. This includes the time spent sleeping due to cost-based delays. |                            |
| Read I/O time          | Time spent reading database blocks by vacuum operations performed on this table                                              | <code>blk_read_time</code> |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Column                  | Description                                                                          | Field/Calculation                |
|-------------------------|--------------------------------------------------------------------------------------|----------------------------------|
| Write I/O time          | Time spent writing database blocks by vacuum operations performed on this table      | blk_write_time                   |
| User CPU time           | User CPU time of vacuuming tables of this database                                   | user_time                        |
| System CPU time         | System CPU time of vacuuming tables of this database                                 | system_time                      |
| Vacuum Vacuum count     | Number of times this table has been manually vacuumed (not counting VACUUM FULL)     | vacuum_count                     |
| Autovacuum Vacuum count | Number of times this table has been vacuumed by the autovacuum daemon                | autovacuum_count                 |
| Total Fetched           | Total number of database blocks fetched by vacuum operations performed on this table | total_blks_read + total_blks_hit |
| Heap Fetched            | Total number of blocks fetched from this table by vacuum operations performed on it  | rel_blks_read + rel_blks_hit     |
| Scanned                 | Number of pages examined by vacuum operations performed on this table                | pages_scanned                    |

The report table “Top tables by analyze time spent” shows top tables by the time spent in manual and automatic analyze. [Table G.57](#) lists columns of this report table. Times are provided in seconds.

**Table G.57. Top tables by analyze time spent**

| Column                    | Description                                                                                                                  | Field/Calculation |

| Analyze Analyze time      | Total time this table was manually analyzed. This includes the time spent sleeping due to cost-based delays.                 |                   |
| AutoAnalyze Analyze time  | Total time this table was analyzed by the autovacuum daemon. This includes the time spent sleeping due to cost-based delays. |                   |
| Analyze Analyze count     | Number of times this table has been manually analyzed                                                                        | analyze_count     |
| AutoAnalyze Analyze count | Number of times this table has been analyzed by the autovacuum daemon                                                        | autoanalyze_count |

The report table “Top indexes by vacuum time spent” is available if [pgpro\\_stats](#) can provide extended vacuum statistics. This table shows top indexes by total time spent vacuuming them. The data is based on the `pgpro_stats_vacuum_indexes` view. [Table G.58](#) lists columns of this report table.

**Table G.58. Top indexes by vacuum time spent**

| Column                  | Description                                                                                    | Field/Calculation                |
|-------------------------|------------------------------------------------------------------------------------------------|----------------------------------|
| DB                      | Database name for the table                                                                    |                                  |
| Tablespace              | Name of the tablespace where the table is located                                              |                                  |
| Schema                  | Schema name for the table                                                                      |                                  |
| Table                   | Table name                                                                                     |                                  |
| Index                   | Index name                                                                                     |                                  |
| Total Vacuum time       | Total time of vacuuming this index                                                             | total_time                       |
| Delay Vacuum time       | Time spent sleeping in a vacuum delay point by vacuum operations performed on this index       | delay_time                       |
| Read I/O time           | Time spent reading database blocks by vacuum operations performed on this index                | blk_read_time                    |
| Write I/O time          | Time spent writing database blocks by vacuum operations performed on this index                | blk_write_time                   |
| User CPU time           | User CPU time of vacuuming this index                                                          | user_time                        |
| System CPU time         | System CPU time of vacuuming this index                                                        | system_time                      |
| Vacuum Vacuum count     | Number of times the underlying table has been manually vacuumed (not counting VACUUM FULL)     | vacuum_count                     |
| Autovacuum Vacuum count | Number of times the underlying table has been vacuumed by the autovacuum daemon                | autovacuum_count                 |
| Total fetched           | Total number of database blocks fetched by vacuum operations performed on the underlying table | total_blks_read + total_blks_hit |
| Index fetched           | Total number of blocks fetched from this index by vacuum operations performed on it            | rel_blks_read + rel_blks_hit     |

The report table “Top tables by blocks vacuum fetched” is available if [pgpro\\_stats](#) can provide extended vacuum statistics. This table shows top tables by blocks fetched vacuuming these tables. The data is based on the `pgpro_stats_vacuum_tables` view. [Table G.59](#) lists columns of this report table.

**Table G.59. Top tables by blocks vacuum fetched**

| Column     | Description                                       | Field/Calculation |
|------------|---------------------------------------------------|-------------------|
| DB         | Database name for the table                       |                   |
| Tablespace | Name of the tablespace where the table is located |                   |
| Schema     | Schema name for the table                         |                   |
| Table      | Table name                                        |                   |

The report table “Top tables by dead tuples vacuum left” is available if [pgpro\\_stats](#) can provide extended vacuum statistics. This table shows top tables by the number of dead tuples left by vacuum due to their visibility in transactions. The data is based on the `pgpro_stats_vacuum_tables` view. [Table G.63](#) lists columns of this report table.

**Table G.63. Top tables by dead tuples vacuum left**

| Column              | Description                                                                                                                                                   | Field/Calculation                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| DB                  | Database name for the table                                                                                                                                   |                                                                                 |

| DB                        | Database name for the table                                                                                                  |                   |
| Tablespace                | Name of the tablespace where the table is located                                                                            |                   |
| Schema                    | Schema name for the table                                                                                                    |                   |
| Table                     | Table name                                                                                                                   |                   |
| Analyze Analyze count     | Number of times this table has been manually analyzed                                                                        | analyze_count     |
| AutoAnalyze Analyze count | Number of times this table has been analyzed by the autovacuum daemon                                                        | autoanalyze_count |
| Analyze Analyze time      | Total time this table was manually analyzed. This includes the time spent sleeping due to cost-based delays.                 |                   |
| AutoAnalyze Analyze time  | Total time this table was analyzed by the autovacuum daemon. This includes the time spent sleeping due to cost-based delays. |                   |
| Ins                       | Number of rows inserted                                                                                                      | n_tup_ins         |
| Upd                       | Number of rows updated, including HOT                                                                                        | n_tup_upd         |
| Del                       | Number of rows deleted                                                                                                       | n_tup_del         |
| Upd (HOT)                 | Number of rows HOT updated                                                                                                   | n_tup_hot_upd     |

The report table “Top indexes by estimated vacuum load” shows top indexes by estimated implicit vacuum load. This load is calculated as the number of vacuum operations performed on the underlying table multiplied by the index size. The data is based on the `pg_stat_all_indexes` view. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. Table G.67 lists columns of this report table.

**Table G.67. Top indexes by estimated vacuum load**

| Column                  | Description                                                                                    | Field/Calculation                                                        |
|-------------------------|------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| DB                      | Database name for the index                                                                    |                                                                          |
| Tablespace              | Name of the tablespace where the index is located                                              |                                                                          |
| Schema                  | Schema name for the underlying table                                                           |                                                                          |
| Table                   | Underlying table name                                                                          |                                                                          |
| Index                   | Index name                                                                                     |                                                                          |
| ~Vacuum bytes           | Vacuum load estimation                                                                         | $(\text{vacuum\_count} + \text{autovacuum\_count}) * \text{index\_size}$ |
| Vacuum Vacuum count     | Number of times this table has been manually vacuumed (not counting <code>VACUUM FULL</code> ) |                                                                          |
| Autovacuum Vacuum count | Number of times this table has been vacuumed by the autovacuum daemon                          |                                                                          |
| IX size                 | Average index size during the report interval                                                  |                                                                          |
| Relsize                 | Average relation size during the report interval                                               |                                                                          |

The report table “Top tables by dead tuples ratio” shows top tables larger than 5 MB by the ratio of dead tuples. Statistics are valid for the last sample in the report interval. The data is based on the `pg_stat_all_tables` view. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. Table G.68 lists columns of this report table.

**Table G.68. Top tables by dead tuples ratio**

| Column  | Description                                                         | Field/Calculation                                                    |
|---------|---------------------------------------------------------------------|----------------------------------------------------------------------|
| DB      | Database name for the table                                         |                                                                      |
| Schema  | Schema name for the table                                           |                                                                      |
| Table   | Table name                                                          |                                                                      |
| Live    | Estimated number of live rows                                       | <code>n_live_tup</code>                                              |
| Dead    | Estimated number of dead rows                                       | <code>n_dead_tup</code>                                              |
| %Dead   | Percentage of dead rows in all table rows                           |                                                                      |
| Last AV | Last time at which this table was vacuumed by the autovacuum daemon | <code>last_autovacuum</code>                                         |
| Size    | Table size                                                          | $\text{pg\_table\_size}() - \text{pg\_relation\_size}(\text{toast})$ |

The report table “Top tables by modified tuples ratio” shows top tables larger than 5 MB by the ratio of modified tuples. Statistics are valid for the last sample in the report interval. The data is based on the `pg_stat_all_tables` view. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. [Table G.69](#) lists columns of this report table.

**Table G.69. Top tables by modified tuples ratio**

| Column  | Description                                                          | Field/Calculation                                                   |
|---------|----------------------------------------------------------------------|---------------------------------------------------------------------|
| DB      | Database name for the table                                          |                                                                     |
| Schema  | Schema name for the table                                            |                                                                     |
| Table   | Table name                                                           |                                                                     |
| Live    | Estimated number of live rows                                        | <code>n_live_tup</code>                                             |
| Dead    | Estimated number of dead rows                                        | <code>n_dead_tup</code>                                             |
| Mod     | Estimated number of rows modified since this table was last analyzed | <code>n_mod_since_analyze</code>                                    |
| %Mod    | Percentage of modified rows in all table rows                        |                                                                     |
| Last AA | Last time at which this table was analyzed by the autovacuum daemon  | <code>last_autoanalyze</code>                                       |
| Size    | Table size                                                           | <code>pg_table_size()</code> - <code>pg_relation_size(toast)</code> |

### G.2.11.11. Cluster settings during the report interval

This section of the report contains a table with Postgres Pro GUC parameters, values of functions `version()`, `pg_postmaster_start_time()`, `pg_conf_load_time()` and the `system_identifier` field of the `pg_control_system()` function during the report interval. The data in the table is grouped under Defined settings and Default settings. [Table G.70](#) lists columns of this report table.

**Table G.70. Cluster settings during the report interval**

| Column    | Description                                                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------|
| Setting   | Name of the parameter                                                                                                                  |
| reset_val | <code>reset_val</code> field of the <code>pg_settings</code> view. Settings changed during the report interval are shown in bold font. |
| Unit      | Unit of the setting                                                                                                                    |
| Source    | Configuration file where this setting is defined, semicolon, line number                                                               |
| Notes     | Timestamp of the sample where this value was first observed                                                                            |

### G.2.11.12. Extension versions during the report interval

This section of the report contains a table that lists installed extension versions found in databases during the report interval. `First seen` and `Last seen` columns are not shown if the extension versions have not changed during the report interval. [Table G.71](#) lists columns of this report table.

**Table G.71. Extension versions during the report interval**

| Column | Description    |
|--------|----------------|
| Name   | Extension name |

| Column     | Description                                                         |
|------------|---------------------------------------------------------------------|
| DB         | Database name                                                       |
| First seen | Timestamp of the sample where this extension version appeared first |
| Last seen  | Timestamp of the sample where this extension version appeared last  |
| Version    | Version name of the extension                                       |

## G.2.12. pgpro\_pwr Diagnostic Tools

pgpro\_pwr provides self-diagnostic tools.

### G.2.12.1. Collecting Detailed Timing Statistics for Sampling Procedures

pgpro\_pwr collects detailed timing statistics of taking samples when the `pgpro_pwr.track_sample_timings` parameter is on. You can get the results from the `v_sample_timings` view. [Table G.72](#) lists columns of this view.

**Table G.72. `v_sample_timings` View**

| Column         | Description                                                                         |
|----------------|-------------------------------------------------------------------------------------|
| server_name    | Name of the server                                                                  |
| sample_id      | Sample identifier                                                                   |
| sample_time    | Time when the sample was taken                                                      |
| sampling_event | Sampling stage. See <a href="#">Table G.73</a> for descriptions of sampling stages. |
| time_spent     | Time spent in the event                                                             |

**Table G.73. `sampling_event` Description**

| Event                       | Description                                                                                                        |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------|
| total                       | Taking the sample (all stages)                                                                                     |
| connect                     | Making dblink connection to the server                                                                             |
| get server environment      | Getting server GUC parameters, available extensions, etc.                                                          |
| collect database stats      | Querying the <code>pg_stat_database</code> view for statistics on databases                                        |
| calculate database stats    | Calculating differential statistics on databases since the previous sample                                         |
| collect tablespace stats    | Querying the <code>pg_tablespace</code> view for statistics on tablespaces                                         |
| collect statement stats     | Collecting statistics on statements using the <code>pg-pro_stats</code> and <code>pg_stat_kcache</code> extensions |
| collect wait sampling stats | Collecting statistics on statements using the <code>pg_wait_sampling</code> extension                              |
| query pg_stat_bgwriter      | Collecting cluster statistics using the <code>pg_stat_bgwriter</code> view                                         |
| query pg_stat_wal           | Collecting cluster WAL statistics using the <code>pg_stat_wal</code> view                                          |
| query pg_stat_io            | Collecting cluster I/O statistics using the <code>pg_stat_io</code> view, available starting with Postgres Pro 16  |

## G.2.13. Important Notes

When using the `pgpro_pwr` extension, be aware of the following:

- Postgres Pro collects execution statistics *after* the execution is complete. If a single execution of a statement lasts for several samples, it will only affect statistics of the last sample (in which the execution completed). Besides, statistics on statements that are still running are unavailable. Maintenance processes, such as vacuum and checkpoint, will update the statistics only on completion.
- Resetting any Postgres Pro statistics may affect the accuracy of the next sample.
- Exclusive locks on relations conflict with calculation of the relation size. If the `take_sample()` function is unable to acquire a lock for a short period of time (3 seconds), it will fail and no sample will be generated.

## G.3. pgpro\_stats

The `pgpro_stats` extension provides a means for tracking planning and execution statistics of all SQL statements executed by a server. It is based on the `pg_stat_statements` module and provides the following additional functionality:

- Storing query plans in addition to query statements.
- Configuring sample rate for statistics collection to reduce overhead.
- Calculating wait event statistics for executed queries.
- Calculating resource usage statistics of statement planning and execution.
- Calculating cache invalidation statistics.
- Calculating additional archiver statistics.
- Providing an interface to statistics about vacuuming databases, tables, and indexes collected by the core system.
- Tracing of application sessions.
- Creating views that emulate other extensions.

### Note

When the server gets shut down, `pgpro_stats` saves the collected statistics to two dump files on disk in the format that depends on the number and order of columns in the `pgpro_stats_statements` and `pgpro_stats_totals` views. If this format has changed in a new `pgpro_stats` version, during the first server restart after upgrading the extension, the saved statistics will fail to be read with an error reported to the log:

```
LOG:  pgpro_stats: could not load statements data file of obsolete format
      "pg_stat/pgpro_stats.stat"
```

or

```
LOG:  pgpro_stats: could not load statements data file of obsolete format
      "pg_stat/pgpro_stats_totals.stat"
```

The contents of the files will be ignored, and respective statistics will be nullified. To learn whether the format has changed, see the [Release Notes](#) for pgpro\_stats version being installed. To retain the previously collected statistics, download them as CSV files before upgrading.

The background information, along with views and types, related to calculating cache invalidation statistics is provided in a separate section [Section G.3.9](#).

### G.3.1. Limitations

- pgpro\_stats can sometimes fail to match identical parameters in the query statement and the corresponding query plan.
- Some SPI queries are not included into statistics.
- Texts and plans of some SPI queries are not normalized.
- pgpro\_stats is incompatible with [pg\\_stat\\_statements](#), as well as other extensions that use parser, planner, or executor hooks to modify parse and plan trees and execution of the queries. Moreover, if both pgpro\_stats and [pg\\_stat\\_statements](#) are on the list of `shared_preload_libraries`, the database server will not start. Note also that in order to dump the final versions of the queries and plans, pgpro\_stats should be the last on the list of `shared_preload_libraries`, but some existing extensions, such as `pg_pathman`, will not work at all unless they are the last on this list.
- pgpro\_stats may not work correctly with third-party extensions that produce `CustomScan` and `ForeignScan` nodes.

### G.3.2. Installation and Setup

pgpro\_stats is provided with Postgres Pro Enterprise as a separate pre-built package `pgpro-stats-ent-14` (for the detailed installation instructions, see [Chapter 17](#)). Once you have pgpro\_stats installed, complete the following steps to enable pgpro\_stats:

1. Add pgpro\_stats to the [shared\\_preload\\_libraries](#) parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'pgpro_stats'
```

2. Restart the Postgres Pro Enterprise instance for the changes to take effect.

Once the server is reloaded, pgpro\_stats starts tracking statistics across all databases of the cluster. If required, you can change the scope of statistics collection or disable it altogether using pgpro\_stats [configuration parameters](#).

3. To access the collected statistics, you have to create pgpro\_stats extension:

```
CREATE EXTENSION pgpro_stats;
```

In addition, query identifier calculation must be enabled in order for pgpro\_stats to be active, which is done automatically if [compute\\_query\\_id](#) is set to `auto` or `on`, or any third-party module that calculates query identifiers is loaded.

### G.3.3. Usage

- [Collecting Statistics on Query Statements and Plans](#)
- [Monitoring Custom Metrics](#)

### G.3.3.1. Collecting Statistics on Query Statements and Plans

Once installed, the `pgpro_stats` extension starts collecting statistics on the executed statements. The collected data is similar to the one provided by `pg_stat_statements`, but also includes information on query plans and wait events for each query type. The statistics is saved into an in-memory ring buffer and is accessible through the `pgpro_stats_statements` view.

By default, `pgpro_stats` collects statistics on all the executed statements that satisfy the `pgpro_stats.track` and `pgpro_stats.track_utility` settings. If performance is a concern, you can set a sample rate for queries using the `pgpro_stats.query_sample_rate` parameter, and `pgpro_stats` will randomly select queries for statistics calculation at the specified rate.

To collect statistics on wait events, `pgpro_stats` uses time-based sampling. Wait events are sampled at the time interval specified by the `pgpro_stats.profile_period` parameter, which is set to 10ms by default. If the sampling shows that the process is waiting, the `pgpro_stats.profile_period` value is added to the wait event duration. Thus, time estimation for each wait event remains valid even if the `pgpro_stats.profile_period` parameter value has changed. If you are not interested in wait event statistics, you can disable wait event sampling by setting the `pgpro_stats.enable_profile` parameter to `false`.

`pgpro_stats_statements.plans` and `pgpro_stats_statements.calls` aren't always expected to match because planning and execution statistics are updated at their respective end phase, and only for successful operations. For example, if a statement is successfully planned but fails during the execution phase, only its planning statistics will be updated. If planning is skipped because a cached plan is used, only its execution statistics will be updated.

As an example, let's create a table with some random data and build an index on this table:

```
CREATE TABLE test AS (SELECT i, random() x FROM generate_series(1,1000000) i);
CREATE INDEX test_x_idx ON test (x);
```

Now run the following query several times using different values for `:x_min` and `:x_max`:

```
select * from test where x >= :x_min and x <= :x_max;
```

The collected statistics should appear in the `pgpro_stats_statements` view:

```
SELECT queryid, query, planid, plan, wait_stats FROM pgpro_stats_statements WHERE query
LIKE 'select * from test where%';
-[ RECORD
  1 ]-----
queryid      | 1109491335754870054
query        | select * from test where x >= $1 and x <= $2
planid       | 8287793242828473388
plan         | Gather
              |   Output: i, x
              |   Workers Planned: 2
              |   -> Parallel Seq Scan on public.test
              |       Output: i, x
              |       Filter: ((test.x >= $3) AND (test.x <= $4))
wait_stats   | {"IO": {"DataFileRead": 10}, "IPC": {"BgWorkerShutdown": 10}, "Total":
              | {"IO": 10, "IPC": 10, "Total": 20}}
-[ RECORD
  2 ]-----
queryid      | 1109491335754870054
query        | select * from test where x >= $1 and x <= $2
planid       | -9045072158333552619
plan         | Bitmap Heap Scan on public.test
              |   Output: i, x
              |   Recheck Cond: ((test.x >= $3) AND (test.x <= $4))
```

## Postgres Pro Modules and Extensions Shipped as Individual Packages

```

|      -> Bitmap Index Scan on test_x_idx
|          Index Cond: ((test.x >= $5) AND (test.x <= $6))
|
wait_stats | {"IO": {"DataFileRead": 40}, "Total": {"IO": 40, "Total": 40}}
-[ RECORD
  3 ]-----
queryid    | 1109491335754870054
query      | select * from test where x >= $1 and x <= $2
planid     | -1062789671372193287
plan       | Seq Scan on public.test
|          Output: i, x
|          Filter: ((test.x >= $3) AND (test.x <= $4))
|
wait_stats | NULL
-[ RECORD
  4 ]-----
queryid    | 1109491335754870054
query      | select * from test where x >= $1 and x <= $2
planid     | -1748292253893834280
plan       | Index Scan using test_x_idx on public.test
|          Output: i, x
|          Index Cond: ((test.x >= $3) AND (test.x <= $4))
|
wait_stats | NULL

```

### G.3.3.2. Monitoring Custom Metrics

With `pgpro_stats`, you can define custom metrics to be monitored. The collected data will be saved into an in-memory ring buffer and then sent to a monitoring system. Unlike direct polling of a database by a monitoring system that can lose some data if the connection is interrupted, this approach allows to get all the collected data regardless of connection issues, as long as this data is still available in the ring buffer.

To set up a custom metric to collect, do the following:

1. For each metric, define all configuration parameters listed in [Section G.3.7.2](#). You must specify a unique numeric identifier of each metric in the parameter names.

For example, to monitor index bloating each 60 seconds, you can define a new metric by setting metrics-related parameters as follows:

```

pgpro_stats.metric_1_name = index_bloat
pgpro_stats.metric_1_query = 'select iname, ibloat, ipages from bloat'
pgpro_stats.metric_1_db = 'postgres'
pgpro_stats.metric_1_user = postgres
pgpro_stats.metric_1_period = '60s'

```

2. Restart the server.

`pgpro_stats` starts collecting statistics on executed statements and saves it into the ring buffer, and the collected data appears in the `pgpro_stats_metrics` view:

```
SELECT * FROM pgpro_stats_metrics;
```

3. If required, set up data export to a monitoring system of your choice.

## G.3.4. Views

### G.3.4.1. The `pgpro_stats_statements` View

The statistics gathered by the module are made available via a view named `pgpro_stats_statements`. This view contains one row for each distinct database ID, user ID and query ID (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in [Table G.76](#).

**Table G.76. pgpro\_stats\_statements Columns**

| Name            | Type   | References                       | Description                                                                                                                           |
|-----------------|--------|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| userid          | oid    | <a href="#">pg_authid</a> .oid   | OID of user who executed the statement                                                                                                |
| dbid            | oid    | <a href="#">pg_database</a> .oid | OID of database in which the statement was executed                                                                                   |
| toplevel        | bool   |                                  | True if the query was executed as a top-level statement (always true if <a href="#">pgpro_stats.track</a> is set to top)              |
| queryid         | bigint |                                  | Internal hash code, computed from the statement's parse tree                                                                          |
| planid          | bigint |                                  | Internal hash code, computed from the statement's plan tree                                                                           |
| query           | text   |                                  | Text of a representative statement                                                                                                    |
| plan            | text   |                                  | The text of the query plan, in the format defined by the <a href="#">pgpro_stats.plan_format</a> configuration parameter              |
| plans           | int8   |                                  | Number of times the statement was planned (if <a href="#">pgpro_stats.track_planning</a> is enabled, otherwise zero)                  |
| total_plan_time | float8 |                                  | Total time spent planning the statement, in milliseconds (if <a href="#">pgpro_stats.track_planning</a> is enabled, otherwise zero).  |
| min_plan_time   | float8 |                                  | Minimum time spent planning the statement, in milliseconds (if <a href="#">pgpro_stats.track_planning</a> is enabled, otherwise zero) |
| max_plan_time   | float8 |                                  | Maximum time spent planning the statement, in milliseconds (if <a href="#">pgpro_stats.track_planning</a> is enabled, otherwise zero) |
| mean_plan_time  | float8 |                                  | Mean time spent planning the statement, in milliseconds (if <a href="#">pgpro_stats.track_planning</a>                                |

|                            |                                        |            | in milliseconds. In Postgres Pro versions lower than 15, contains zero.                                                                                                                                                                                                     |
| jit_emission_count         | int8                                   |            | Number of times code has been emitted by the statement. In Postgres Pro versions lower than 15, contains zero.                                                                                                                                                              |
| jit_emission_time          | float8                                 |            | Total time spent by the statement on emitting code, in milliseconds. In Postgres Pro versions lower than 15, contains zero.                                                                                                                                                 |
| jit_deform_count           | int8                                   |            | Total number of tuple deform functions JIT-compiled by the statement. In Postgres Pro versions lower than 17, contains zero.                                                                                                                                                |
| jit_deform_time            | float8                                 |            | Total time spent by the statement on JIT-compiling tuple deform functions, in milliseconds. In Postgres Pro versions lower than 17, contains zero.                                                                                                                          |
| parallel_workers_to_launch | bigint                                 |            | Number of parallel workers planned to be launched. In Postgres Pro versions lower than 18, contains zero.                                                                                                                                                                   |
| parallel_workers_launched  | bigint                                 |            | Number of parallel workers actually launched. In Postgres Pro versions lower than 18, contains zero.                                                                                                                                                                        |
| wait_stats                 | jsonb                                  |            | A <code>jsonb</code> object containing statistics on wait events, for each execution of the query that uses the corresponding plan. Each statistic is provided in milliseconds and is a multiple of the <a href="#">pgpro_stats.profile_period</a> configuration parameter. |
| inval_msgs                 | <a href="#">pgpro_stats_inval_msgs</a> |            | Number of cache invalidation messages by type generated by the statement (if this is support-                                                                                                                                                                               |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Name               | Type                     | References | Description                                                                                                                                     |
|--------------------|--------------------------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
|                    |                          |            | ed by the server, otherwise zero).                                                                                                              |
| stats_since        | timestamp with time zone |            | Time at which statistics gathering started for this statement                                                                                   |
| minmax_stats_since | timestamp with time zone |            | Time at which min/max statistics gathering started for this statement (fields min_plan_time , max_plan_time , min_exec_time and max_exec_time ) |

Take into account that like [pg\\_stat\\_statements](#), pgpro\_stats normalizes into one record those DML queries (containing `SELECT`, `INSERT`, `UPDATE`, `DELETE` and `MERGE` commands) that have equivalent structures according to some internal hash value. Being compared this way, two queries are normally considered equal if they are semantically equivalent up to constants included in the queries. All the other commands are, however, compared strictly as query texts. When the value of a constant in a query is ignored for comparison with other queries, this constant is replaced in the pgpro\_stats output with a symbol of a parameter, such as, `$k`, where `k` is a positive integer. If a query already contains parameters, the initial value of `k` equals the number following the last number of a `$n` parameter in the original query text. If there are no parameters, the initial value of `k` equals 1. Note that sometimes hidden parameter symbols affect this numbering. For example, PL/pgSQL uses such hidden symbols to insert values of function local variables into queries, so a PL/pgSQL statement `SELECT i + 1 INTO j` will be represented as `SELECT i + $2` in the normalized query text.

In some cases, queries with visibly different texts might get merged into a single `pgpro_stats_statements` entry. Normally this will happen only for semantically equivalent queries, but there is a small chance of hash collisions causing unrelated queries to be merged into one entry. (This cannot happen for queries belonging to different users or databases, however.)

pgpro\_stats uses a similar technique to normalize plan texts. When doing so, an attempt is made to associate numbers of constants in the plan text with the corresponding numbers of constants in the query text. If such an attempt appears unsuccessful for a certain constant in the plan text, it is assigned the number following the maximum number of a constant replaced in the query text. For example, consider the query:

```
SELECT 1::int, 'abc'::VARCHAR(3), 2::int;
```

pgpro\_stats will replace numbers of constants in the query text and in the text of the corresponding plan as follows:

```
postgres=# SELECT query, plan FROM pgpro_stats_statements;
```

| query                                       | plan                  |
|---------------------------------------------|-----------------------|
| <hr style="border-top: 1px dashed black;"/> |                       |
| SELECT \$1::int, \$2::VARCHAR(3), \$3::int  | Result                |
| +                                           |                       |
|                                             | Output: \$1, \$4, \$3 |
| +                                           |                       |

In this plan text, it appeared possible to associate constants numbered 1 and 3 from the query text, but not the constant numbered 2, and the latter was replaced with the number following the maximum number in the query text, that is, number 4.

Replacement of numbers in plan texts has an exception for version numbers of XML documents. If in the original query such a number is represented with a constant, e.g., `'1.0'`, it is retained as is in the plan text rather than replaced with `$k`. If the version number of an XML document is represented with an expression, replacement of constants follows usual rules.

### G.3.4.2. The `pgpro_stats_totals` View

The aggregate statistics gathered by the module are made available via a view named `pgpro_stats_totals`. This view contains one row for each distinct object (up to the maximum number of distinct objects that the module can track). The columns of the view are shown in [Table G.77](#).

**Table G.77. `pgpro_stats_totals` Columns**

| Name                             | Type                               | Description                                                                                                                                         |
|----------------------------------|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object_type</code>         | text                               | Type of the object for which aggregated statistics are collected: "cluster", "database", "user", "client_addr", "application", "backend", "session" |
| <code>object_id</code>           | bigint                             | ID of the object: oid for databases and users, pid for backends, sid for sessions, NULL for others                                                  |
| <code>object_name</code>         | text                               | Textual name of the object or NULL                                                                                                                  |
| <code>queries_planned</code>     | int8                               | Number of queries planned                                                                                                                           |
| <code>total_plan_time</code>     | float8                             | Total time spent in the planning of statements, in milliseconds                                                                                     |
| <code>total_plan_rusage</code>   | <a href="#">pgpro_stats_rusage</a> | Aggregate resource usage statistics of the statement planning                                                                                       |
| <code>queries_executed</code>    | int8                               | Number of queries executed                                                                                                                          |
| <code>total_exec_time</code>     | float8                             | Total time spent in the execution of statements, in milliseconds                                                                                    |
| <code>total_exec_rusage</code>   | <a href="#">pgpro_stats_rusage</a> | Aggregate resource usage statistics of the statement execution                                                                                      |
| <code>rows</code>                | int8                               | Total number of rows retrieved or affected by the statements                                                                                        |
| <code>shared_blks_hit</code>     | int8                               | Total number of shared block cache hits by the statements                                                                                           |
| <code>shared_blks_read</code>    | int8                               | Total number of shared blocks read by the statements                                                                                                |
| <code>shared_blks_dirtied</code> | int8                               | Total number of shared blocks dirtied by the statements                                                                                             |
| <code>shared_blks_written</code> | int8                               | Total number of shared blocks written by the statements                                                                                             |
| <code>local_blks_hit</code>      | int8                               | Total number of local block cache hits by the statements                                                                                            |
| <code>local_blks_read</code>     | int8                               | Total number of local blocks read by the statements                                                                                                 |
| <code>local_blks_dirtied</code>  | int8                               | Total number of local blocks dirtied by the statements                                                                                              |
| <code>local_blks_written</code>  | int8                               | Total number of local blocks written by the statements                                                                                              |
| <code>temp_blks_read</code>      | int8                               | Total number of temp blocks read by the statements                                                                                                  |
| <code>temp_blks_written</code>   | int8                               | Total number of temp blocks written by the statements                                                                                               |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Name                  | Type    | Description                                                                                                                                                                                   |
|-----------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| shared_blk_read_time  | float8  | Total time the statements spent reading shared blocks, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero)                                                        |
| shared_blk_write_time | float8  | Total time the statements spent writing shared blocks, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero)                                                        |
| local_blk_read_time   | float8  | Total time the statements spent reading local blocks, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero). In Postgres Pro versions lower than 17, contains zero. |
| local_blk_write_time  | float8  | Total time the statements spent writing local blocks, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero). In Postgres Pro versions lower than 17, contains zero. |
| temp_blk_read_time    | float8  | Total time the statements spent reading temp blocks, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero). In Postgres Pro versions lower than 15, contains zero.  |
| temp_blk_write_time   | float8  | Total time the statements spent writing temp blocks, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero). In Postgres Pro versions lower than 15, contains zero.  |
| wal_records           | int8    | Total number of WAL records generated by the statements                                                                                                                                       |
| wal_fpi               | int8    | Total number of WAL full page images generated by the statements                                                                                                                              |
| wal_bytes             | numeric | Total amount of WAL bytes generated by the statements                                                                                                                                         |
| wal_buffers_full      | bigint  | Total number of times the WAL buffers became full. In Postgres Pro versions lower than 18, contains zero.                                                                                     |
| jit_functions         | int8    | Total number of functions JIT-compiled by the statements. In Postgres Pro versions lower than 15, contains zero.                                                                              |
| jit_generation_time   | float8  | Total time spent by the statements on generating JIT code, in milliseconds. In Postgres Pro versions lower than 15, contains zero.                                                            |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Name                       | Type   | Description                                                                                                                                                                                                                              |
|----------------------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| jit_inlining_count         | int8   | Number of times functions used in the statements have been in-lined. In Postgres Pro versions lower than 15, contains zero.                                                                                                              |
| jit_inlining_time          | float8 | Total time spent by the statements on inlining functions, in milliseconds. In Postgres Pro versions lower than 15, contains zero.                                                                                                        |
| jit_optimization_count     | int8   | Number of times the statements have been optimized. In Postgres Pro versions lower than 15, contains zero.                                                                                                                               |
| jit_optimization_time      | float8 | Total time spent by the statements on optimizing, in milliseconds. In Postgres Pro versions lower than 15, contains zero.                                                                                                                |
| jit_emission_count         | int8   | Number of times code has been emitted by the statements. In Postgres Pro versions lower than 15, contains zero.                                                                                                                          |
| jit_emission_time          | float8 | Total time spent by the statements on emitting code, in milliseconds. In Postgres Pro versions lower than 15, contains zero.                                                                                                             |
| jit_deform_count           | int8   | Total number of tuple deform functions JIT-compiled by the statements. In Postgres Pro versions lower than 17, contains zero.                                                                                                            |
| jit_deform_time            | float8 | Total time spent by the statements on JIT-compiling tuple deform functions, in milliseconds. In Postgres Pro versions lower than 17, contains zero.                                                                                      |
| parallel_workers_to_launch | bigint | Number of parallel workers planned to be launched by the statements. In Postgres Pro versions lower than 18, contains zero.                                                                                                              |
| parallel_workers_launched  | bigint | Number of parallel workers actually launched by the statements. In Postgres Pro versions lower than 18, contains zero.                                                                                                                   |
| wait_stats                 | jsonb  | A <code>jsonb</code> object containing statistics on wait events for each execution of the queries. Each statistic is provided in milliseconds and is a multiple of the <code>pgpro_stats.profile_period</code> configuration parameter. |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Name         | Type                                   | Description                                                                                                                                           |
|--------------|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| inval_msgs   | <a href="#">pgpro_stats_inval_msgs</a> | Number of cache invalidation messages by type generated by the statements (if this is supported by the server, otherwise zero).                       |
| cache_resets | int4                                   | Number of shared cache resets (only for cluster, databases and backends). Gets incremented for a backend when it receives a full cache reset message. |
| stats_since  | timestamp with time zone               | Time at which statistics gathering started for the statements                                                                                         |

### G.3.4.3. The `pgpro_stats_info` View

The statistics of the `pgpro_stats` module itself are tracked and made available via a view named `pgpro_stats_info`. This view contains only a single row. The columns of the view are shown in [Table G.78](#).

**Table G.78. `pgpro_stats_info` Columns**

| Name        | Type                     | Description                                                                                                                                                                                                |
|-------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dealloc     | bigint                   | Total number of times <code>pgpro_stats_statements</code> entries about the least-executed statements were deallocated because more distinct statements than <a href="#">pgpro_stats.max</a> were observed |
| stats_reset | timestamp with time zone | Time at which all statistics in the <code>pgpro_stats_statements</code> view were last reset                                                                                                               |

### G.3.4.4. The `pgpro_stats_metrics` View

The metrics gathered by `pgpro_stats` are displayed in the `pgpro_stats_metrics` view. The table below describes the columns of the view.

**Table G.79. `pgpro_stats_metrics` Columns**

| Name          | Type       | Description                                                                                                                                             |
|---------------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| metric_number | int4       | A unique ID of the collected metric assigned by user. This ID is included into parameter names that define the metric.                                  |
| metric_name   | text       | The name of the metric defined by the <code>pgpro_stats.metric_N_name</code> parameter                                                                  |
| db_name       | text       | The name of the database for which a particular metric was collected                                                                                    |
| ts            | timestampz | The time when the metric value got calculated                                                                                                           |
| value         | jsonb      | The result of the query used for metric measurement. It is serialized in <code>jsonb</code> as an array of objects received via <code>to_jsonb()</code> |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Name | Type | Description                                                                                                                                                                                |
|------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|      |      | <code>resulting_row</code> ). If an error occurs, a single object is returned that contains <code>code</code> , <code>message</code> , <code>detail</code> , and <code>hint</code> fields. |

### G.3.4.5. The `pgpro_stats_archiver` View

The `pgpro_stats_archiver` view will contain one row showing data about the archiver process of the cluster.

**Table G.80. `pgpro_stats_archiver` Columns**

| Column                            | Type                                  | Description                                                |
|-----------------------------------|---------------------------------------|------------------------------------------------------------|
| <code>archived_count</code>       | <code>bigint</code>                   | Number of WAL files that have been successfully archived   |
| <code>last_archived_wal</code>    | <code>text</code>                     | Name of the last WAL file successfully archived            |
| <code>last_archived_time</code>   | <code>timestamp with time zone</code> | Time of the last successful archive operation              |
| <code>failed_count</code>         | <code>bigint</code>                   | Number of failed attempts for archiving WAL files          |
| <code>last_failed_wal</code>      | <code>text</code>                     | Name of the WAL file of the last failed archival operation |
| <code>last_failed_time</code>     | <code>timestamp with time zone</code> | Time of the last failed archival operation                 |
| <code>active_time</code>          | <code>int8</code>                     | Overall time that the archiver process was active          |
| <code>archive_command_time</code> | <code>int8</code>                     | Overall execution time of the archive command              |
| <code>stats_reset</code>          | <code>timestamp with time zone</code> | Time at which these statistics were last reset             |

### G.3.4.6. The `pgpro_stats_vacuum_database` View

#### Important

Starting with Postgres Pro 16, this view contains no data because the statistics to be displayed are available through the catalog view `pg_stats_vacuum_database` (see [System Views](#) for details).

The `pgpro_stats_vacuum_database` view will contain one row for each database in the current cluster, showing statistics about vacuuming that database. These statistics are collected by the core system as explained in [Section 27.2](#). The table below describes the columns of the view.

**Table G.81. `pgpro_stats_vacuum_database` Columns**

| Column                       | Type              | Description                                                                    |
|------------------------------|-------------------|--------------------------------------------------------------------------------|
| <code>dbid</code>            | <code>oid</code>  | OID of a database                                                              |
| <code>total_blks_read</code> | <code>int8</code> | Number of database blocks read by vacuum operations performed on this database |
| <code>total_blks_hit</code>  | <code>int8</code> | Number of times database blocks were found in the buffer cache                 |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Column             | Type    | Description                                                                                                                                                         |
|--------------------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                    |         | by vacuum operations performed on this database                                                                                                                     |
| total_blks_dirtied | int8    | Number of database blocks dirtied by vacuum operations performed on this database                                                                                   |
| total_blks_written | int8    | Number of database blocks written by vacuum operations performed on this database                                                                                   |
| wal_records        | int8    | Total number of WAL records generated by vacuum operations performed on this database                                                                               |
| wal_fpi            | int8    | Total number of WAL full page images generated by vacuum operations performed on this database                                                                      |
| wal_bytes          | numeric | Total amount of WAL bytes generated by vacuum operations performed on this database                                                                                 |
| blk_read_time      | float8  | Time spent reading database blocks by vacuum operations performed on this database, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero) |
| blk_write_time     | float8  | Time spent writing database blocks by vacuum operations performed on this database, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero) |
| delay_time         | float8  | Time spent sleeping in a vacuum delay point by vacuum operations performed on this database, in milliseconds (see <a href="#">Section 19.4.4</a> for details)       |
| system_time        | float8  | System CPU time of vacuuming this database, in milliseconds                                                                                                         |
| user_time          | float8  | User CPU time of vacuuming this database, in milliseconds                                                                                                           |
| total_time         | float8  | Total time of vacuuming this database, in milliseconds                                                                                                              |
| interrupts         | int4    | Number of times vacuum operations performed on this database were interrupted on any errors                                                                         |

### G.3.4.7. The pgpro\_stats\_vacuum\_tables View

#### Important

Starting with Postgres Pro 16, this view contains no data because the statistics to be displayed are available through the catalog view `pg_stats_vacuum_tables` (see [System Views](#) for details).

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

The `pgpro_stats_vacuum_tables` view will contain one row for each table in the current database (including TOAST tables), showing statistics about vacuuming that specific table. These statistics are collected by the core system as explained in [Section 27.2](#). The table below describes the columns of the view.

**Table G.82. `pgpro_stats_vacuum_tables` Columns**

| Column                          | Type              | Description                                                                                                                                                                                                                                 |
|---------------------------------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>relid</code>              | <code>oid</code>  | OID of a table                                                                                                                                                                                                                              |
| <code>schema</code>             | <code>name</code> | Name of the schema this table is in                                                                                                                                                                                                         |
| <code>relname</code>            | <code>name</code> | Name of this table                                                                                                                                                                                                                          |
| <code>total_blks_read</code>    | <code>int8</code> | Number of database blocks read by vacuum operations performed on this table                                                                                                                                                                 |
| <code>total_blks_hit</code>     | <code>int8</code> | Number of times database blocks were found in the buffer cache by vacuum operations performed on this table                                                                                                                                 |
| <code>total_blks_dirtied</code> | <code>int8</code> | Number of database blocks dirtied by vacuum operations performed on this table                                                                                                                                                              |
| <code>total_blks_written</code> | <code>int8</code> | Number of database blocks written by vacuum operations performed on this table                                                                                                                                                              |
| <code>rel_blks_read</code>      | <code>int8</code> | Number of blocks vacuum operations read from this table                                                                                                                                                                                     |
| <code>rel_blks_hit</code>       | <code>int8</code> | Number of times blocks of this table were already found in the buffer cache by vacuum operations, so that a read was not necessary (this only includes hits in the Postgres Pro buffer cache, not the operating system's file system cache) |
| <code>pages_scanned</code>      | <code>int8</code> | Number of pages examined by vacuum operations performed on this table                                                                                                                                                                       |
| <code>pages_removed</code>      | <code>int8</code> | Number of pages removed from the physical storage by vacuum operations performed on this table                                                                                                                                              |
| <code>pages_frozen</code>       | <code>int8</code> | Number of times vacuum operations marked pages of this table as all-frozen in the visibility map                                                                                                                                            |
| <code>pages_all_visible</code>  | <code>int8</code> | Number of times vacuum operations marked pages of this table as all-visible in the visibility map                                                                                                                                           |
| <code>tuples_deleted</code>     | <code>int8</code> | Number of dead tuples vacuum operations deleted from this table                                                                                                                                                                             |
| <code>tuples_frozen</code>      | <code>int8</code> | Number of tuples of this table that vacuum operations marked as frozen                                                                                                                                                                      |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Column                | Type    | Description                                                                                                                                                      |
|-----------------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dead_tuples           | int8    | Number of dead tuples vacuum operations left in this table due to their visibility in transactions                                                               |
| index_vacuum_count    | int8    | Number of times indexes on this table were vacuumed                                                                                                              |
| rev_all_frozen_pages  | int8    | Number of times the all-frozen mark in the visibility map was removed for pages of this table                                                                    |
| rev_all_visible_pages | int8    | Number of times the all-visible mark in the visibility map was removed for pages of this table                                                                   |
| wal_records           | int8    | Total number of WAL records generated by vacuum operations performed on this table                                                                               |
| wal_fpi               | int8    | Total number of WAL full page images generated by vacuum operations performed on this table                                                                      |
| wal_bytes             | numeric | Total amount of WAL bytes generated by vacuum operations performed on this table                                                                                 |
| blk_read_time         | float8  | Time spent reading database blocks by vacuum operations performed on this table, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero) |
| blk_write_time        | float8  | Time spent writing database blocks by vacuum operations performed on this table, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero) |
| delay_time            | float8  | Time spent sleeping in a vacuum delay point by vacuum operations performed on this table, in milliseconds (see <a href="#">Section 19.4.4</a> for details)       |
| system_time           | float8  | System CPU time of vacuuming this table, in milliseconds                                                                                                         |
| user_time             | float8  | User CPU time of vacuuming this table, in milliseconds                                                                                                           |
| total_time            | float8  | Total time of vacuuming this table, in milliseconds                                                                                                              |
| interrupts            | integer | Number of times vacuum operations performed on this table were interrupted on any errors                                                                         |

Columns `total_*`, `wal_*` and `blk_*` include data on vacuuming indexes on this table, while columns `system_time` and `user_time` only include data on vacuuming the heap.

### G.3.4.8. The `pgpro_stats_vacuum_indexes` View

#### Important

Starting with Postgres Pro 16, this view contains no data because the statistics to be displayed are available through the catalog view `pg_stats_vacuum_indexes` (see [System Views](#) for details).

The `pgpro_stats_vacuum_indexes` view will contain one row for each index in the current database (including TOAST table indexes), showing statistics about vacuuming that specific index. These statistics are collected by the core system as explained in [Section 27.2](#). The table below describes the columns of the view.

**Table G.83. `pgpro_stats_vacuum_indexes` Columns**

| Column                          | Type              | Description                                                                                                                                                                                                                                 |
|---------------------------------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>relid</code>              | <code>oid</code>  | OID of an index                                                                                                                                                                                                                             |
| <code>schema</code>             | <code>name</code> | Name of the schema this index is in                                                                                                                                                                                                         |
| <code>relname</code>            | <code>name</code> | Name of this index                                                                                                                                                                                                                          |
| <code>total_blks_read</code>    | <code>int8</code> | Number of database blocks read by vacuum operations performed on this index                                                                                                                                                                 |
| <code>total_blks_hit</code>     | <code>int8</code> | Number of times database blocks were found in the buffer cache by vacuum operations performed on this index                                                                                                                                 |
| <code>total_blks_dirtied</code> | <code>int8</code> | Number of database blocks dirtied by vacuum operations performed on this index                                                                                                                                                              |
| <code>total_blks_written</code> | <code>int8</code> | Number of database blocks written by vacuum operations performed on this index                                                                                                                                                              |
| <code>rel_blks_read</code>      | <code>int8</code> | Number of blocks vacuum operations read from this index                                                                                                                                                                                     |
| <code>rel_blks_hit</code>       | <code>int8</code> | Number of times blocks of this index were already found in the buffer cache by vacuum operations, so that a read was not necessary (this only includes hits in the Postgres Pro buffer cache, not the operating system's file system cache) |
| <code>pages_deleted</code>      | <code>int8</code> | Number of pages deleted by vacuum operations performed on this index                                                                                                                                                                        |
| <code>tuples_deleted</code>     | <code>int8</code> | Number of dead tuples vacuum operations deleted from this index                                                                                                                                                                             |
| <code>wal_records</code>        | <code>int8</code> | Total number of WAL records generated by vacuum operations performed on this index                                                                                                                                                          |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Column         | Type    | Description                                                                                                                                                      |
|----------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| wal_fpi        | int8    | Total number of WAL full page images generated by vacuum operations performed on this index                                                                      |
| wal_bytes      | numeric | Total amount of WAL bytes generated by vacuum operations performed on this index                                                                                 |
| blk_read_time  | float8  | Time spent reading database blocks by vacuum operations performed on this index, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero) |
| blk_write_time | float8  | Time spent writing database blocks by vacuum operations performed on this index, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero) |
| delay_time     | float8  | Time spent sleeping in a vacuum delay point by vacuum operations performed on this index, in milliseconds (see <a href="#">Section 19.4.4</a> for details)       |
| system_time    | float8  | System CPU time of vacuuming this index, in milliseconds                                                                                                         |
| user_time      | float8  | User CPU time of vacuuming this index, in milliseconds                                                                                                           |
| total_time     | float8  | Total time of vacuuming this index, in milliseconds                                                                                                              |
| interrupts     | integer | Number of times vacuum operations performed on this index were interrupted on any errors                                                                         |

## G.3.5. Data Types

### G.3.5.1. The pgpro\_stats\_rusage Type

`pgpro_stats_rusage` is a record type that contains resource usage statistics of statement planning/execution. The fields of this type are shown in [Table G.84](#).

**Table G.84. pgpro\_stats\_rusage Fields**

| Name        | Type             | Description                                     |
|-------------|------------------|-------------------------------------------------|
| reads       | bigint           | Number of bytes read by the filesystem layer    |
| writes      | bigint           | Number of bytes written by the filesystem layer |
| user_time   | double precision | User CPU time used                              |
| system_time | double precision | System CPU time used                            |
| minflts     | bigint           | Number of page reclaims (soft page faults)      |
| majflts     | bigint           | Number of page faults (hard page faults)        |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Name     | Type   | Description                            |
|----------|--------|----------------------------------------|
| nswaps   | bigint | Number of swaps                        |
| msgsnds  | bigint | Number of IPC messages sent            |
| msgrcvsv | bigint | Number of IPC messages received        |
| nsignals | bigint | Number of signals received             |
| nvcsws   | bigint | Number of voluntary context switches   |
| nivcsws  | bigint | Number of involuntary context switches |

## G.3.6. Functions

`pgpro_stats_statements_reset(userid Oid, dbid Oid, queryid bigint, planid bigint, minmax_only boolean)` returns timestamp with time zone

`pgpro_stats_statements_reset` discards statistics gathered so far by `pgpro_stats` corresponding to the specified `userid`, `dbid`, `queryid`, and `planid`. If any of the parameters are not specified, the default value 0(invalid) is used for each of them and the statistics that match with other parameters will be reset. If no parameter is specified or all the specified parameters are 0(invalid), it will discard all statistics. If all statistics in the `pgpro_stats_statements` view are discarded, it will also reset the statistics in the `pgpro_stats_info` view. When `minmax_only` is true only the values of minimum and maximum planning and execution time will be reset (i.e. `min_plan_time`, `max_plan_time`, `min_exec_time` and `max_exec_time` fields). The default value for `minmax_only` parameter is false. Time of last min/max reset performed is shown in `minmax_stats_since` field of the `pgpro_stats_statements` view. This function returns the time of a reset. This time is saved to `stats_reset` field of `pgpro_stats_info` view or to `minmax_stats_since` field of the `pgpro_stats_statements` view if the corresponding reset was actually performed. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

### Note

As statistics in the `pgpro_stats_vacuum_database`, `pgpro_stats_vacuum_tables`, and `pgpro_stats_vacuum_indexes` views are collected by the core system, to reset them, call the `pg_stat_reset()` function (see [Section 27.2.25](#) for details).

`pgpro_stats_statements(showtext boolean)` returns setof record

The `pgpro_stats_statements` view is defined in terms of a function also named `pgpro_stats_statements`. Users can also call the `pgpro_stats_statements` function directly, and by specifying `showtext := false` make query text be omitted (that is, the `OUT` argument that corresponds to the view's query column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all `pgpro_stats` itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the `pgpro_stats_statements` data.

`pgpro_stats_statements_filtered(showtext boolean, userid oid, dboid oid, queryid bigint, planid bigint)` returns setof record

The `pgpro_stats_statements_filtered` function allows you to filter statistics similar to those provided in the `pgpro_stats_statements` view by one or several fields specified by the parameters `userid`, `dbid`, `queryid`, and `planid`. If any of these parameters are not specified, the default value 0(invalid) is used for each of them and the statistics that match with other parameters will be re-

turned. `showtext` is true by default. Specifying `showtext := false` makes query text be omitted, as explained for the `pgpro_stats_statements` function. Because `pgpro_stats_statements_filtered` only selects the needed rows, it returns the statistics faster than a query like this:

```
SELECT * FROM pgpro_stats_statements WHERE userid = ? AND dbid = ? AND queryid = ?
AND planid = ?;
```

`pgpro_stats_info()` returns record

`pgpro_stats_info` view is defined in terms of a function also named `pgpro_stats_info`. Users can also call the `pgpro_stats_info` function directly.

`pgpro_stats_totals_reset(type text, id bigint)` returns timestamp with timezone

`pgpro_stats_totals_reset` discards statistics gathered so far by `pgpro_stats` corresponding to the specified object type and `id`. If no parameter is specified or the `type` parameter is set to 0, all statistics will be discarded. If `type` is set to a valid object type, then if `id` is specified, then statistics will be discarded only for the specified object, else, statistics will be discarded for all objects of the specified type. Otherwise, no statistics will be discarded. This function returns the time of a reset. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

`pgpro_stats_totals()` returns setof record

The `pgpro_stats_totals` view is defined in terms of a function also named `pgpro_stats_totals`. Users can also call the `pgpro_stats_totals` function directly.

`pgpro_stats_metrics()` returns setof record

Defines the `pgpro_stats_metrics` view, which is described in detail in [Table G.79](#).

`pgpro_stats_get_archiver()` returns setof record

Defines the `pgpro_stats_archiver` view, which is described in detail in [Table G.80](#).

`pgpro_stats_wal_sender_crc_errors()` returns bigint

In Postgres Pro Enterprise, returns the number of errors detected by the WAL sender process when the `wal_sender_check_crc` parameter is on. In Postgres Pro Standard, returns zero. Note that this counter is reset to zero when the cluster restarts.

`pgpro_stats_vacuum_database(dboid oid)` returns setof record

Defines the row of the `pgpro_stats_vacuum_database` view, which is described in detail in [Table G.81](#), for the database specified by `dboid`.

`pgpro_stats_vacuum_tables(dboid oid, relid oid)` returns setof record

Defines the row of the `pgpro_stats_vacuum_tables` view, which is described in detail in [Table G.82](#), for the database specified by `dboid` and table specified by `relid`. If `relid = 0`, the statistics for each table in the specified database are returned.

`pgpro_stats_vacuum_indexes(dboid oid, relid oid)` returns setof record

Defines the row of the `pgpro_stats_vacuum_indexes` view, which is described in detail in [Table G.83](#), for the database specified by `dboid` and index specified by `relid`. If `relid = 0`, the statistics for each index in the specified database are returned.

### G.3.6.1. Functions for Creating Views that Emulate Other Extensions

`pgpro_stats` can create views similar to those available in `pg_stat_statements` and `pg_stat_kcache` extensions. Specifically, `pg_stat_statements`, `pg_stat_statements_info`, `pg_stat_kcache` and `pg_stat_kcache_detail` views can be created. Each view is only created in a Postgres Pro version if it is available in `pg_stat_statements/pg_stat_kcache` extension for the same version of Postgres Pro/PostgreSQL. For example, the `pg_stat_statements_info` view is only created in Postgres Pro versions starting with 14. The following functions enable creating these views:

`pgpro_stats_create_pg_stat_statements_compatible_views()` returns void

Creates `pg_stat_statements` and `pg_stat_statements_info` views.

`pgpro_stats_create_pg_stat_kcache_compatible_views()` returns void

Creates `pg_stat_kcache` and `pg_stat_kcache_detail` views.

By default, these functions can only be executed by superusers. Access may be granted to others using `GRANT`.

To create `pg_stat_statements*` views, drop the `pg_stat_statements` extension if it was previously installed and call the function:

```
select pgpro_stats_create_pg_stat_statements_compatible_views();
```

To create `pg_stat_kcache*` views, drop the `pg_stat_kcache` extension if it was previously installed and call the function:

```
select pgpro_stats_create_pg_stat_kcache_compatible_views();
```

Once the views are created, you can work with them as if the `pg_stat_statements/pg_stat_kcache` extension is installed.

If you need to remove the views created earlier, do it in a regular way:

```
drop view pg_stat_statements;  
drop view pg_stat_statements_info;  
drop view pg_stat_kcache;  
drop view pg_stat_kcache_detail;
```

## G.3.7. Configuration Parameters

### G.3.7.1. General Settings

`pgpro_stats.max (integer)`

`pgpro_stats` only collects statistics about most frequent queries. The less frequently a query appears during the server operation, the less probable its inclusion in the statistics. Rare queries are almost immediately evicted from the statistics by more frequent queries. The `pgpro_stats.max` parameter defines the maximum number of unique pairs (normalized query text, normalized plan text) tracked by the module, (i.e., the maximum number of rows in the `pgpro_stats_statements` view). The larger this value, the larger the number of queries for which the information is stored. But this is achieved at the cost of reduced server performance when waiting for locks trying to access the statistics table in the shared memory and when periodically collecting garbage in the file with texts of queries and plans. The default value is 5000. This parameter can only be set at server start.

`pgpro_stats.max_totals (integer)`

`pgpro_stats.max_totals` is the maximum number of objects tracked by the module (i.e., the maximum number of rows in the `pgpro_stats_totals` view). If more distinct objects than that are observed, information about least-used objects is discarded. The default value is 1000. This parameter can only be set at server start.

`pgpro_stats.track (enum)`

`pgpro_stats.track` controls which statements are counted by the module. Specify `top` to track top-level statements (those issued directly by clients), `all` to also track nested statements (such as statements invoked within functions) with nesting level not greater than 100, or `none` to disable statement statistics collection. The default value is `top`. Only superusers can change this setting.

`pgpro_stats.track_utility (boolean)`

`pgpro_stats.track_utility` controls whether utility commands are tracked by the module. Utility commands are all those other than `SELECT`, `INSERT`, `UPDATE` and `DELETE`. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_planning` (boolean)

`pgpro_stats.track_planning` controls whether planning operations and duration are tracked by the module. Enabling this parameter may incur a noticeable performance penalty, especially when statements with identical query structure are executed by many concurrent connections which compete to update a small number of `pgpro_stats.statements` entries. The default value is `off`. Only superusers can change this setting.

`pgpro_stats.track_totals` (boolean)

`pgpro_stats.track_totals` controls whether aggregate statistics for objects (cluster, users, databases etc.) are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_cluster` (boolean)

`pgpro_stats.track_cluster` controls whether aggregate statistics for the cluster are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_databases` (boolean)

`pgpro_stats.track_databases` controls whether aggregate statistics for the databases are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_users` (boolean)

`pgpro_stats.track_users` controls whether aggregate statistics for the users are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_applications` (boolean)

`pgpro_stats.track_applications` controls whether aggregate statistics for the applications (whose names are set by [application\\_name](#)) are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_client_addr` (boolean)

`pgpro_stats.track_client_addr` controls whether aggregate statistics for the client IP addresses are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_backends` (boolean)

`pgpro_stats.track_backends` controls whether aggregate statistics for the backends are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.save` (boolean)

`pgpro_stats.save` specifies whether to save statement statistics across server shutdowns. If it is `off` then statistics are neither saved at shutdown nor reloaded at server start. The default value is `on`. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`pgpro_stats.plan_format` (text)

`pgpro_stats.plan_format` selects the `EXPLAIN` format for the query plan. Possible values are `text`, `xml`, `json`, and `yaml`. The default value is `text`. Changing this parameter requires a server restart.

`pgpro_stats.enable_profile` (boolean)

`pgpro_stats.enable_profile` enables sampling of wait events for separate statements. The default value is `true`. Changing this parameter requires a server restart.

`pgpro_stats.query_sample_rate` (float)

As `pgpro_stats` only collects statistics about most frequent queries, and rare queries are not included in the statistics, you can reduce the effect of the statistics collection on the server performance. This is possible because some time later than the statistics collection starts, almost all the statistics collected by the module will contain queries that are not very infrequent, and the set of types of the collected queries will not further change much if the value of [pgpro\\_stats.max](#) is sufficient

and the average frequency for most of the frequent queries has no significant changes with the periods larger than the observation time. Such a stationary distribution of collected queries can also be achieved by increasing the time of the statistics collection, for example, twice, but only adding each second query to the statistics instead of every query, or considering each query, but adding queries to the statistics randomly, with a given probability. In this example, it equals 0.5. This allows you to considerably reduce the server load at the cost of increasing the time of the statistics collection. `pgpro_stats.query_sample_rate` is the parameter to implement this approach. For example: if `pgpro_stats.query_sample_rate` is set to 0.2 (1/5), in five hours of the server operation under the above conditions, the statistics will be collected that is similar to the statistics collected with `pgpro_stats.query_sample_rate = 1` in an hour.

You can set up `pgpro_stats.query_sample_rate` by experiment. Choose the observation time depending on the environment of the server operation, for example: one hour. Look at the collected statistics an hour after the start and then an hour later without resetting the statistics. If the main difference appears to be in the increased number of collected queries (`calls`) rather than in the type of the queries, you can safely reduce `pgpro_stats.query_sample_rate` twice. In the case of a considerable difference in the types of the collected queries, increase the observation time and/or the `pgpro_stats.max` parameter.

The default value is 1.0. Changing this parameter requires a server restart.

`pgpro_stats.profile_period` (integer)

`pgpro_stats.profile_period` specifies the period, in milliseconds, during which to sample wait events. The default value is 10. Only superusers can change this setting.

`pgpro_stats.metrics_buffer_size` (integer)

`pgpro_stats.metrics_buffer_size` specifies the size of the ring buffer used for collecting statistical metrics. The default value is 16kB. Changing this parameter requires a server restart.

`pgpro_stats.metrics_workers` (integer)

`pgpro_stats.metrics_workers` specifies the number of workers used to collect statistical metrics. If this parameter is set to 2 or higher, one of the workers serves as the primary worker distributing queries to other workers. If only one worker is available, it gets reloaded to connect to different databases. Setting this parameter to 0 disables metrics collection. The default value is 2. Changing this parameter requires a server restart.

`pgpro_stats.stats_temp_directory` (string)

`pgpro_stats.stats_temp_directory` specifies the directory with the external file to store query texts. This can be a path relative to the data directory or an absolute path. Changing this parameter requires a server restart.

### G.3.7.2. Metrics Settings

The following parameters can be used to define a custom metric to collect. The *N* placeholder in the parameter name serves as a unique identifier of the metric to which this setting should apply; it must be set to a non-negative integer for each metric.

When you add these parameters for a new metric, you have to restart the server for the changes to take effect.

`pgpro_stats.metric_N_name` (text)

The name of metric *N*. This name will be displayed in the `metric_name` column of the `pgpro_stats_metrics` view.

`pgpro_stats.metric_N_query` (text)

The query statement that defines the metric to collect.

`pgpro_stats.metric_N_period` (integer)

The time interval at which to collect metric *N*, in milliseconds. Default: 60000 ms

`pgpro_stats.metric_N_db` (text)

The list of databases for which to collect metric *N*. Database names must be separated by commas. You can specify the `*` character to select all databases in the cluster except the template databases. If you need to analyze the template databases as well, you have to specify them explicitly.

`pgpro_stats.metric_N_user` (text)

The name of the user on behalf of which to collect metric *N*. This user must have access to the database for which the metric is collected.

### G.3.8. Tracing of Application Sessions

In `pgpro_stats`, tracing of application sessions is implemented. It is based on filters, which trigger logging the execution of queries that match filtering conditions. Queries and their `EXPLAIN` output are logged in so-called *trace files* specified by the user or in the system log file (if the trace file is not specified). Filters are stored in a table located in the shared memory. The rows of this table represent filters, and the columns contain filtering conditions and `EXPLAIN` options to be used (see [EXPLAIN](#) for details). You should fill this table with filters to start tracing of queries.

Once a database administrator adds a filter in any session, all subsequent executions of queries that match the filter conditions will be traced by all sessions of the instance without a need in the server restart. In other words, filters can be added, deleted, or updated “on the fly”, and tracing with these filters immediately starts for existing and future sessions.

#### Note

Operations of adding, deleting, or updating filters are not transactional. Changes to the table of filters are not rolled back together with the transaction where these changes were made.

Columns of the table that stores filters are also called *filter attributes*. They are described in [Table G.85](#).

**Table G.85. Filter Attributes**

| Name                   | Type    | Description                                                                                                                                                                                                                                                                                                                                                         |
|------------------------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>filter_id</code> | integer | Unique filter ID, which is automatically assigned to a filter when it is created, numbered from 1.                                                                                                                                                                                                                                                                  |
| <code>active</code>    | boolean | With the value of <code>false</code> , the filter is not active, which means that queries matching this filter are not logged. Default: <code>true</code> .                                                                                                                                                                                                         |
| <code>alias</code>     | name    | Filter name, which can be specified for convenience. Only shown in the output of the <code>pgpro_stats_trace_show()</code> function. Default: empty string.                                                                                                                                                                                                         |
| <code>tracefile</code> | name    | Name of the trace file, where queries matching the filter and their <code>EXPLAIN</code> output are logged. If this filename is not specified, logging is done to the system log with the log level specified by <code>pgpro_stats_trace_log_level</code> . Trace files are created in <code>PGDATA/pg_stat</code> directory and have <code>trace</code> extension. |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Name                | Type    | Description                                                                |
|---------------------|---------|----------------------------------------------------------------------------|
| pid                 | integer | Process ID of the backend that executes the statement                      |
| database_name       | name    | Name of the database where the statement is executed                       |
| client_addr         | name    | IP address of the client connected to this backend                         |
| application_name    | name    | Name of the application that invoked execution of the statement            |
| username            | name    | Name of the user who executes the statement                                |
| queryid             | bigint  | Internal hash code, computed from the statement's parse tree               |
| planid              | bigint  | Internal hash code, computed from the statement's plan tree                |
| duration            | float8  | Time spent in the planning and execution of the statement, in milliseconds |
| plan_time           | float8  | Time spent in the planning of the statement, in milliseconds               |
| exec_time           | float8  | Time spent in the execution of the statement, in milliseconds              |
| user_time           | float8  | User CPU time used in planning and execution of the statement              |
| system_time         | float8  | System CPU time used in planning and execution of the statement            |
| rows                | int8    | Total number of rows retrieved or affected by the statement                |
| shared_blks_hit     | int8    | Total number of shared block cache hits by the statement                   |
| shared_blks_read    | int8    | Total number of shared blocks read by the statement                        |
| shared_blks_fetched | int8    | Total number of shared blocks fetched from buffers by the statement        |
| shared_blks_dirtied | int8    | Total number of shared blocks dirtied by the statement                     |
| shared_blks_written | int8    | Total number of shared blocks written by the statement                     |
| local_blks_hit      | int8    | Total number of local block cache hits by the statement                    |
| local_blks_read     | int8    | Total number of local blocks read by the statement                         |
| local_blks_fetched  | int8    | Total number of local blocks fetched from buffers by the statement         |
| local_blks_dirtied  | int8    | Total number of local blocks dirtied by the statement                      |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Name               | Type    | Description                                                                                                                                                                   |
|--------------------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| local_blks_written | int8    | Total number of local blocks written by the statement                                                                                                                         |
| temp_blks_read     | int8    | Total number of temp blocks read by the statement                                                                                                                             |
| temp_blks_written  | int8    | Total number of temp blocks written by the statement                                                                                                                          |
| wal_bytes          | numeric | Total amount of WAL bytes generated by the statement                                                                                                                          |
| total_wait_time    | float8  | Total time execution of this statement spent waiting                                                                                                                          |
| total_inval_msgs   | bigint  | Total number of cache invalidation messages generated by the statement (if this is supported by the server)                                                                   |
| explain_analyze    | boolean | If true, the EXPLAIN output will be logged with the ANALYZE option. By default, defined by the <a href="#">pgpro_stats.explain_analyze_default</a> configuration parameter.   |
| explain_verbose    | boolean | If true, the EXPLAIN output will be logged with the VERBOSE option. By default, defined by the <a href="#">pgpro_stats.explain_verbose_default</a> configuration parameter.   |
| explain_costs      | boolean | If true, the EXPLAIN output will be logged with the COSTS option. By default, defined by the <a href="#">pgpro_stats.explain_costs_default</a> configuration parameter.       |
| explain_settings   | boolean | If true, the EXPLAIN output will be logged with the SETTINGS option. By default, defined by the <a href="#">pgpro_stats.explain_settings_default</a> configuration parameter. |
| explain_buffers    | boolean | If true, the EXPLAIN output will be logged with the BUFFERS option. By default, defined by the <a href="#">pgpro_stats.explain_buffers_default</a> configuration parameter.   |
| explain_wal        | boolean | If true, the EXPLAIN output will be logged with the WAL option. By default, defined by the <a href="#">pgpro_stats.explain_wal_default</a> configuration parameter.           |
| explain_timing     | boolean | If true, the EXPLAIN output will be logged with the TIMING option. By default, defined by the <a href="#">pgpro_stats.explain_timing_default</a> configuration parameter.     |
| explain_format     | text    | The value of the FORMAT option of EXPLAIN to be logged, which can                                                                                                             |

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

| Name                   | Type    | Description                                                                                                                                                                                                                                                                                                |
|------------------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        |         | be TEXT, XML, JSON, or YAML. By default, defined by the <code>pgpro_stats.plan_format</code> configuration parameter.                                                                                                                                                                                      |
| <code>time_info</code> | boolean | If true, includes additional information in the session-tracing output in the format defined by <code>explain_format : pid, duration</code> in milliseconds, start time — start time of the query execution, and stop time — end time of the query execution. See <a href="#">Example G.2</a> for details. |

Filter attributes can be divided into the following groups:

- Control attributes, from `filter_id` to `tracefile` in [Table G.85](#).
- Identification attributes, from `pid` to `planid` in [Table G.85](#).
- Threshold attributes, from `duration` to `total_inval_msgs` in [Table G.85](#).
- Attributes that only control the output to the trace file or system log file and do not affect filtering. Most of them specify the `EXPLAIN` options. These are the attributes starting with `explain_analyze` up to the end of [Table G.85](#).

Query execution will be traced if both of these conditions are met:

- For all the specified identification attributes of the filter, the values of the respective characteristics of the query are the same as the values of these attributes.
- For all the specified threshold attributes of the filter, the values of the respective characteristics of the query are greater than or equal to the limits specified in these attributes.

It is allowed not to assign values to attributes. For all the attributes except `active`, you can also explicitly assign the value of `NULL`. If the value of a control attribute is undefined or it was explicitly set to `NULL`, this attribute will be assigned the default value shown in [Table G.85](#). For identification and threshold attributes, undefined or `NULL` values mean that queries will not be filtered by the respective characteristic. If no values are defined for all identification and all threshold attributes, all the queries are taken to be matching this filter and will be logged. If the attributes specifying `EXPLAIN` options are undefined, the default values defined by the configuration parameters will be used (see [Section G.3.8.2](#) for details).

### Warning

Although when specifying a filter, you can assign values to any combination of filter attributes, bear in mind that a too general filter will lead to an excessive size of the trace file and will affect the performance more than desired as the main performance overhead is associated with writing to the trace file rather than with checking the filter conditions.

## G.3.8.1. Session-Tracing Functions

Specialized functions enable creation, update and deletion of query filters:

`pgpro_stats_trace_insert(VARIADIC "any")` returns integer

Adds a filter to the list of session-tracing filters. A filter must be passed as a sequence of alternating key-value pairs, where the key is the name of the filter attribute from [Table G.85](#) except `filter_id`. For example:

```
pgpro_stats_trace_insert('pid', 42, 'database_name', 'main', 'explain_analyze',
true)
```

Key-value pairs are position-independent: they can be provided in any order, independently of the order of attributes in [Table G.85](#). Some of the attributes can be missing from the sequence. Such attributes will be assigned the default values. Returns the unique `filter_id`, which the function assigns to the added filter.

`pgpro_stats_trace_update(filter_id integer, VARIADIC "any")` returns boolean

Updates a session-tracing filter defined by `filter_id`. Filter attributes to update must be passed as a sequence of alternating key-value pairs, where the key is the name of the filter attribute from [Table G.85](#) except `filter_id`. Key-value pairs are position-independent: they can be provided in any order, independently of the order of attributes in [Table G.85](#). Filter attributes whose values are not explicitly specified will not be changed. The value of NULL for identification and threshold attributes resets the values of these attributes, which means that a query will match the conditions of the updated filter regardless of the respective characteristics. Returns `true` on success and `false` otherwise.

`pgpro_stats_trace_delete(filter_id integer)` returns boolean

Deletes a session-tracing filter defined by `filter_id`. Returns `true` on success and `false` otherwise.

`pgpro_stats_trace_reset()` returns integer

Removes all session-tracing filters. Returns the number of removed filters. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

`pgpro_stats_trace_show()` returns setof record

Displays the contents of the table of filters, whose columns are shown in [Table G.85](#).

### G.3.8.2. Session-Tracing Configuration Parameters

The following parameters can be used to configure session-tracing logging. Note that `pgpro_stats.explain_*_default` settings define the logging behavior when the corresponding `explain_*` filter attributes (from [Table G.85](#)) are not specified or explicitly set to NULL.

`pgpro_stats.explain_analyze_default` (boolean)

If `true`, the `EXPLAIN` output will be logged with the `ANALYZE` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_verbose_default` (boolean)

If `true`, the `EXPLAIN` output will be logged with the `VERBOSE` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_costs_default` (boolean)

If `true`, the `EXPLAIN` output will be logged with the `COSTS` option and without it if `false`. The default value is `true`. Only superusers can change this setting.

`pgpro_stats.explain_settings_default` (boolean)

If `true`, the `EXPLAIN` output will be logged with the `SETTINGS` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_buffers_default` (boolean)

If `true`, the `EXPLAIN` output will be logged with the `BUFFERS` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_wal_default` (boolean)

If `true`, the `EXPLAIN` output will be logged with the `WAL` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_timing_default` (boolean)

If `true`, the `EXPLAIN` output will be logged with the `TIMING` option and without it if `false`. The default value is `true`. Only superusers can change this setting.

`pgpro_stats.trace_log_level` (enum)

Defines the log level at which the `EXPLAIN` output will be logged to the system log file (when the trace file is not specified). Valid values are `DEBUG5`, `DEBUG4`, `DEBUG3`, `DEBUG2`, `DEBUG1`, `INFO`, `NOTICE`, `WARNING`, and `LOG`. The default value is `LOG`.

`pgpro_stats.trace_query_text_size` (int)

Defines the maximum size of query texts in the session-tracing output, in kilobytes. If the size of the query text in kilobytes is larger, it is trimmed to the maximum size. If this parameter is not specified, the default value of zero is used, which means that the whole query texts are output.

### G.3.8.3. Examples Related to Session Tracing

#### Example G.1. Usage of Session-Tracing Functions

Let's add the filter first:

```
SELECT pgpro_stats_trace_insert('alias', 'first', 'pid', pg_backend_pid(),
    'explain_analyze', true);
```

Let's add the filter second and specify logging to the trace file `second_tf.trace`:

```
SELECT pgpro_stats_trace_insert('alias', 'second', 'database_name', current_database(),
    'explain_costs', false, 'tracefile', 'second_tf');
```

You can view the table with filters as follows:

```
\x auto
SELECT * from pgpro_stats_trace_show();
```

```
-[ RECORD 1 ]-----+-----
filter_id      | 1
active         | t
alias          | first
tracefile      |
pid            | 243183
database_name  |
client_addr    |
application_name |
username       |
queryid        |
planid         |
duration       |
plan_time      |
exec_time      |
user_time      |
system_time    |
rows           |
shared_blks_hit |
shared_blks_read |
shared_blks_fetched |
shared_blks_dirtied |
shared_blks_written |
local_blks_hit |
local_blks_read |
local_blks_fetched |
local_blks_dirtied |
local_blks_written |
temp_blks_read  |
```

Postgres Pro Modules  
and Extensions Shipped  
as Individual Packages

|                          |           |
|--------------------------|-----------|
| temp_blks_written        |           |
| wal_bytes                |           |
| total_wait_time          |           |
| total_inval_msgs         |           |
| explain_analyze          | t         |
| explain_verbose          | f         |
| explain_costs            | t         |
| explain_settings         | f         |
| explain_buffers          | f         |
| explain_wal              | f         |
| explain_timing           | t         |
| explain_format           | text      |
| time_info                | f         |
| -[ RECORD 2 ]-----+----- |           |
| filter_id                | 2         |
| active                   | t         |
| alias                    | second    |
| tracefile                | second_tf |
| pid                      |           |
| database_name            | postgres  |
| client_addr              |           |
| application_name         |           |
| username                 |           |
| queryid                  |           |
| planid                   |           |
| duration                 |           |
| plan_time                |           |
| exec_time                |           |
| user_time                |           |
| system_time              |           |
| rows                     |           |
| shared_blks_hit          |           |
| shared_blks_read         |           |
| shared_blks_fetched      |           |
| shared_blks_dirtied      |           |
| shared_blks_written      |           |
| local_blks_hit           |           |
| local_blks_read          |           |
| local_blks_fetched       |           |
| local_blks_dirtied       |           |
| local_blks_written       |           |
| temp_blks_read           |           |
| temp_blks_written        |           |
| wal_bytes                |           |
| total_wait_time          |           |
| total_inval_msgs         |           |
| explain_analyze          | f         |
| explain_verbose          | f         |
| explain_costs            | f         |
| explain_settings         | f         |
| explain_buffers          | f         |
| explain_wal              | f         |
| explain_timing           | f         |
| explain_format           | text      |
| time_info                | f         |

The following query matches the conditions of both filters, so it must be logged in the system log file and in the specified trace file:

```
SELECT 1 as result;
```

The following is the output to the system log file:

```
2023-04-18 04:52:53.242 MSK [63112] LOG:  Filter 1 triggered explain of the plan:
Query Text: SELECT 1 as result;
Result (cost=0.00..0.01 rows=1 width=4) (actual time=0.003..0.003 rows=1 loops=1)
```

And the following is the output to the `second_tf.trace` trace file:

```
Query Text: SELECT 1 as result;
Result
```

Let's delete the first filter:

```
SELECT pgpro_stats_trace_delete(1);
```

Let's also change `pid` to 2 for the second filter

```
SELECT pgpro_stats_trace_update(2, 'pid', 2);
```

When you execute the query

```
SELECT 2 as result;
```

it does not get logged to `second_tf.trace`.

Now let's remove all filters from the table:

```
SELECT pgpro_stats_trace_reset();
```

### Example G.2. Session-Tracing Output with `time_info = true`

The following is an example of the session-tracing output in the JSON format when `time_info = true`:

```
{
  "Pid": 123456,
  "Duration ms": 0.094691,
  "Start time": "2025-01-12 15:39:27.580447+03",
  "Stop time": "2025-01-12 15:39:27.587802+03",
  "Query Text": "SELECT 2 AS Result;",
  "Plan": {
    "Node Type": "Result",
    "Parallel Aware": false,
    "Async Capable": false,
    "Startup Cost": 0.00,
    "Total Cost": 0.01,
    "Plan Rows": 1,
    "Plan Width": 4
  }
}
```

## G.3.9. Cache Invalidation Metrics

Among the rest, `pgpro_stats` can collect cache invalidation statistics. This section provides some background information needed to better understand related metrics.

Each backend has its local cache, which allows you to minimize accesses for meta information on tables, for example, to the system catalogs. If a backend changes the meta information, this information must be updated in other backends' caches. This is implemented by sending invalidation messages through a queue: the backend that changed the meta information on some object sends an appropriate message to the queue.

All backends get invalidation messages from the queue. Depending on whether the object for which the invalidation message was received is cached, the backend either ignores the message (when the object is

not cached) or updates its cache (when the object is cached). In `pgpro_stats`, most invalidation message counters, unless explicitly stated otherwise for certain counters, are incremented when backends just generate messages, which will only be sent to the queue upon commit of the appropriate transaction. Note that the counters will remain incremented if the transaction is rolled back, although the message will not be sent to the queue.

When a backend that is adding messages to the queue figures out that the queue size reached a certain limit, it starts a cleanup by deleting messages already processed by all backends, and if backends are found that heavily fall behind and thus delay the cleanup, they get a reset signal, which forces them to reset all their caches.

### G.3.9.1. The `pgpro_stats_inval_status` View

The `pgpro_stats_inval_status` view shows one row with the current status of the cache invalidation global queue. The columns of the view are shown in [Table G.86](#).

**Table G.86. `pgpro_stats_inval_status` Columns**

| Name                                  | Type              | Description                                                                   |
|---------------------------------------|-------------------|-------------------------------------------------------------------------------|
| <code>num_inval_messages</code>       | <code>int8</code> | Current number of invalidation messages in the queue                          |
| <code>num_inval_queue_cleanups</code> | <code>int8</code> | Number of invalidation queue cleanups done to prevent its overflow            |
| <code>num_inval_queue_resets</code>   | <code>int4</code> | Number of cache resets for backends that fail to process messages fast enough |

In a working system, `num_inval_messages` usually approximately equals 4000, which means that the queue is pretty full. The speed of the `num_inval_queue_cleanups` growth is determined by how fast invalidation messages are generated. Growth of `num_inval_queue_resets` is normally zero, and non-zero growth indicates either too fast generation of messages or delays in processing messages by backends. Monitoring `num_inval_queue_cleanups` and `num_inval_queue_resets` may in some cases allow you to detect problematic backend/backends as described below.

If for a certain time interval, `num_inval_queue_cleanups` considerably increased, while `num_inval_queue_resets` did not, this indicates that invalidation messages are generated faster and/or backends process them more slowly, but backends still manage to process messages before the queue overflows.

If for a time interval, `num_inval_queue_cleanups` did not considerably increase, while `num_inval_queue_resets` did, this definitely indicates a delay in processing messages by backend(s), and the `cache_resets` column of the `pgpro_stats_totals` view allows you to figure out which backend(s) to blame.

If for a time interval, both counters considerably increased, this also indicates that invalidation messages are generated faster and/or backends process them more slowly, but this time backends fail to process messages before the queue overflows. The `cache_resets` column of the `pgpro_stats_totals` view allows you detect which backend(s) delay message processing. In this case, it is not possible to definitely conclude whether too fast generation of messages or a delay in message processing accounts for the growth of `num_inval_queue_resets`. However, the `totals` counter of the `pgpro_stats_inval_msgs` view may help here. If the change of this counter for that interval is pretty the same as for a previous interval of the same length, you can definitely conclude that the growth is caused by backend delays.

The `pgpro_stats_inval_status` view can be defined in terms of a function:

```
pgpro_stats_inval_status() returns record
```

Defines the `pgpro_stats_inval_status` view, which is described in detail in [Table G.86](#).

### G.3.9.2. The `pgpro_stats_inval_msgs` Type

The `pgpro_stats_statements` and `pgpro_stats_totals` views for each corresponding object, show a record of the `pgpro_stats_inval_msgs` record type containing counters for cache invalidation messages. The fields of the type are shown in [Table G.87](#).

**Table G.87. `pgpro_stats_inval_msgs` Fields**

| Name                      | Type                | Description                                                                                                       |
|---------------------------|---------------------|-------------------------------------------------------------------------------------------------------------------|
| <code>total</code>        | <code>bigint</code> | Total number of invalidation messages                                                                             |
| <code>catcache</code>     | <code>bigint</code> | Number of selective catalog cache invalidation messages                                                           |
| <code>catalog</code>      | <code>bigint</code> | Number of whole catalog cache invalidation messages                                                               |
| <code>relcache</code>     | <code>bigint</code> | Number of selective relation cache invalidation messages                                                          |
| <code>relcache_all</code> | <code>bigint</code> | Number of whole relation cache invalidation messages                                                              |
| <code>smgr</code>         | <code>bigint</code> | Number of invalidation messages of open relation files. Gets incremented when the messages are sent to the queue. |
| <code>relmap</code>       | <code>bigint</code> | Number of relation map cache invalidation messages. Gets incremented when the messages are sent to the queue.     |
| <code>snapshot</code>     | <code>bigint</code> | Number of catalog snapshot invalidation messages                                                                  |

## G.3.10. Authors

Postgres Professional, Moscow, Russia

---

# Appendix H. Third-Party Modules and Extensions Shipped as Individual Packages

This appendix contains third-party modules and extensions that are made available in Postgres Pro Enterprise as individual packages. These packages are listed in [Section 17.1.6.1](#), and the documentation for each module explains which package to choose to install it. [Appendix F](#) and [Appendix G](#) cover more modules and extensions included in the Postgres Pro Enterprise distribution. Note also the following extensions that are shipped as individual packages: orafce, pldebugger and plv8 (see [Table 17.3](#) for details).

## H.1. oracle\_fdw

The `oracle_fdw` module is a Postgres Pro extension that provides a Foreign Data Wrapper for easy and efficient access to Oracle databases, including pushdown of `WHERE` conditions and required columns as well as comprehensive `EXPLAIN` support.

### H.1.1. Installation

The `oracle_fdw` extension is provided with Postgres Pro Enterprise as a separate pre-built package `oracle-fdw-ent-14` (for the detailed installation instructions, see [Chapter 17](#)). `oracle_fdw` requires Oracle Instant Client version 19.5.

For RPM-based systems (RHEL, SUSE, Red OS, ROSA, ALT Linux), download the `oracle-instantclient` RPM and install it using `rpm`. If you use a Debian-based system (Ubuntu, Astra Linux), you have to either convert the RPM package to a Debian package using `alien`, and then install it using `dpkg`, or download the ZIP archive of the client and extract the contents of the archive into the `/opt/oracle` directory.

Once you have Postgres Pro Enterprise installed, create the `oracle_fdw` extension:

```
CREATE EXTENSION oracle_fdw;
```

That will define the required functions and create a foreign data wrapper.

Note that the extension version as shown by the `psql \dx` command or the system catalog `pg_available_extensions` is *not* the installed version of `oracle_fdw`. To get the `oracle_fdw` version, use the [oracledb\\_diag](#) function.

### H.1.2. Internals

`oracle_fdw` sets the `MODULE` of the Oracle session to `postgres` and the `ACTION` to the backend process number. This can help identifying the Oracle session and allows you to trace it with `DBMS_MONITOR.SERV_MOD_ACT_TRACE_ENABLE`.

`oracle_fdw` uses Oracle array interface to avoid unnecessary client-server round-trips. The batch size can be configured with the [prefetch](#) table option and is set to 50 by default.

Rather than using a `PLAN_TABLE` to explain an Oracle query (which would require such a table to be created in the Oracle database), `oracle_fdw` uses execution plans stored in the library cache. For that, an Oracle query is *explicitly described*, which forces Oracle to parse the query. The hard part is to find the `SQL_ID` and `CHILD_NUMBER` of the statement in `V$SQL` because the `SQL_TEXT` column contains only the first 1000 bytes of the query. Therefore, `oracle_fdw` adds a comment to the query that contains a hash of the query text. This is used to search in `V$SQL`. The actual execution plan or cost information is retrieved from `V$SQL_PLAN`.

`oracle_fdw` uses transaction isolation level `SERIALIZABLE` on the Oracle side, which corresponds to Postgres Pro's `REPEATABLE READ`. This is necessary because a single Postgres Pro statement can lead to multiple Oracle queries (e.g. during a nested loop join) and the results need to be consistent. Unfortunately, the Oracle implementation of `SERIALIZABLE` has certain quirks; see the [Problems](#) section for more.

The Oracle transaction is committed immediately before the local transaction commits, so that a completed Postgres Pro transaction guarantees that the Oracle transaction has completed. However, there is a small chance that the Postgres Pro transaction cannot complete even though the Oracle transaction is committed. This cannot be avoided without using two-phase transactions and a transaction manager, which is beyond what a foreign data wrapper can reasonably provide. Prepared statements involving Oracle are not supported for the same reason.

### H.1.3. Short Simple Example

This is an example how to use `oracle_fdw`. More detailed information is provided in the sections [Options](#) and [Usage](#). You should also read the [documentation on foreign data](#) and the commands referenced there.

For the sake of this example, let's assume you can connect to Oracle as the operating system user `postgres` (or whoever starts the Postgres Pro server) with the following command:

```
sqlplus orauser/orapwd@//dbserver.mydomain.com:1521/ORADB
```

That means that the Oracle client and the environment are set up correctly. It is also assumed that `oracle_fdw` has been installed (see the [Installation](#) section).

We want to access a table defined like this:

```
SQL> DESCRIBE oratab
      Name                               Null?    Type
-----
ID                                NOT NULL NUMBER(5)
TEXT                                VARCHA2 (30)
FLOATING                           NOT NULL NUMBER(7,2)
```

Then configure `oracle_fdw` as a Postgres Pro superuser like this:

```
pgdb=# CREATE EXTENSION oracle_fdw;
pgdb=# CREATE SERVER oradb FOREIGN DATA WRAPPER oracle_fdw
      OPTIONS (dbserver '//dbserver.mydomain.com:1521/ORADB');
```

You can use other naming methods or local connections, see the description of [dbserver](#) below.

It is a good idea to use a superuser only where really necessary, so let's allow a normal user to use the foreign server (this is not required for the example to work but recommended):

```
pgdb=# GRANT USAGE ON FOREIGN SERVER oradb TO pguser;
```

Then you can connect to Postgres Pro as `pguser` and define the following:

```
pgdb=> CREATE USER MAPPING FOR pguser SERVER oradb
      OPTIONS (user 'orauser', password 'orapwd');
```

You can use external authentication to avoid storing Oracle passwords.

```
pgdb=> CREATE FOREIGN TABLE oratab (
      id          integer          OPTIONS (key 'true') NOT NULL,
      text        character varying(30),
      floating    double precision NOT NULL
    ) SERVER oradb OPTIONS (schema 'ORAUSER', table 'ORATAB');
```

Remember that the table and schema name (the latter is optional) must normally be in uppercase.

Now you can use the table like a regular Postgres Pro table.

## H.1.4. Usage

### H.1.4.1. Oracle Permissions

The Oracle user will need the `CREATE SESSION` privilege and the right to select from the table or view in question. Note that `oracle_fdw` accesses the Oracle table at query planning time to get its definition. This happens *before* permissions on the foreign table are checked. Consequently, you may receive an Oracle error if you try to access a foreign table on which you have no permissions in Postgres Pro. This is expected and no security problem.

For `EXPLAIN VERBOSE`, the user will also need `SELECT` privileges on `V$SQL` and `V$SQL_PLAN`.

### H.1.4.2. Connections

`oracle_fdw` caches Oracle connections because it is expensive to create an Oracle session for each individual query. All connections are automatically closed when the Postgres Pro session ends.

The `close_connections` function can be used to close all cached Oracle connections. This can be useful for long-running sessions that do not access foreign tables all the time and want to avoid blocking the resources needed by an open Oracle connection. You cannot call this function inside a transaction that modifies Oracle data.

### H.1.4.3. Columns

When you define a foreign table, the columns of the Oracle table are mapped to the Postgres Pro columns in the order of their definition.

`oracle_fdw` will only include those columns in the Oracle query that are actually needed by the Postgres Pro query.

The Postgres Pro table can have more or less columns than the Oracle table. If it has more columns, and these columns are used, you will receive a warning and `NULL` values will be returned.

If you want to `UPDATE` or `DELETE`, make sure that the `key` option is set on all columns that belong to the table's primary key. Failure to do so will result in errors.

### H.1.4.4. Data Types

You must define the Postgres Pro columns with data types that `oracle_fdw` can translate (see the conversion table below). This restriction is only enforced if the column actually gets used, so you can define “dummy” columns for untranslatable data types as long as you don't access them (this trick only works with `SELECT`, not when modifying foreign data). If an Oracle value exceeds the size of the Postgres Pro column (e.g., the length of a `varchar` column or the maximal `integer` value), you will receive a runtime error.

These conversions are automatically handled by `oracle_fdw`:

| Oracle type | Possible PostgreSQL types |
|-------------|---------------------------|
| CHAR        | char, varchar, text       |
| NCHAR       | char, varchar, text       |
| VARCHAR     | char, varchar, text       |
| VARCHAR2    | char, varchar, text, json |
| NVARCHAR2   | char, varchar, text       |
| CLOB        | char, varchar, text, json |
| LONG        | char, varchar, text       |
| RAW         | uuid, bytea               |
| BLOB        | bytea                     |

|                                   |                                                                                  |
|-----------------------------------|----------------------------------------------------------------------------------|
| BFILE                             | bytea (read-only)                                                                |
| LONG RAW                          | bytea                                                                            |
| NUMBER                            | numeric, float4, float8, char, varchar, text                                     |
| NUMBER(n,m) with m<=0             | numeric, float4, float8, int2, int4, int8,<br>      boolean, char, varchar, text |
| FLOAT                             | numeric, float4, float8, char, varchar, text                                     |
| BINARY_FLOAT                      | numeric, float4, float8, char, varchar, text                                     |
| BINARY_DOUBLE                     | numeric, float4, float8, char, varchar, text                                     |
| DATE                              | date, timestamp, timestamptz, char, varchar, text                                |
| TIMESTAMP                         | date, timestamp, timestamptz, char, varchar, text                                |
| TIMESTAMP WITH TIME ZONE          | date, timestamp, timestamptz, char, varchar, text                                |
| TIMESTAMP WITH<br>LOCAL TIME ZONE | date, timestamp, timestamptz, char, varchar, text<br>                            |
| INTERVAL YEAR TO MONTH            | interval, char, varchar, text                                                    |
| INTERVAL DAY TO SECOND            | interval, char, varchar, text                                                    |
| XMLTYPE                           | xml, char, varchar, text                                                         |
| MDSYS.SDO_GEOMETRY                | geometry (see "PostGIS support" below)                                           |

If a NUMBER is converted to a boolean, 0 means false, everything else true.

Inserting or updating XMLTYPE only works with values that do not exceed the maximum length of the VARCHAR2 data type (4000 or 32767, depending on the MAX\_STRING\_SIZE parameter).

NCLOB is currently not supported because Oracle cannot automatically convert it to the client encoding.

If you want to convert TIMESTAMP WITH LOCAL TIME ZONE to timestamp, consider setting the set\_time-zone option on the foreign server.

If you need conversions exceeding the above, define an appropriate view in Oracle or Postgres Pro.

#### H.1.4.5. WHERE Conditions and ORDER BY Clauses

Postgres Pro will use all applicable parts of the WHERE clause as a filter for the scan. The Oracle query that oracle\_fdw constructs will contain a WHERE clause corresponding to these filter criteria whenever such a condition can safely be translated to Oracle SQL. This feature, also known as *push-down* of WHERE clauses, can greatly reduce the number of rows retrieved from Oracle and may enable Oracle's optimizer to choose a good plan for accessing the required tables.

Similarly, ORDER BY clauses will be pushed down to Oracle wherever possible. Note that no ORDER BY condition that sorts by a character string will be pushed down as the sort orders in Postgres Pro and Oracle cannot be guaranteed to be the same.

To make use of that, try to use simple conditions for the foreign table. Choose Postgres Pro column data types that correspond to Oracle's types because otherwise conditions cannot be translated.

The expressions now(), transaction\_timestamp(), current\_timestamp, current\_date, and local-timestamp will be translated correctly.

The output of EXPLAIN will show the Oracle query used so you can see which conditions were translated to Oracle and how.

#### H.1.4.6. Joins Between Foreign Tables

oracle\_fdw can push down joins to the Oracle server, that is, a join between two foreign tables will lead to a single Oracle query that performs the join on the Oracle side.

There are some restrictions when this can happen:

- Both tables must be defined on the same foreign server.
- Joins between three or more tables won't be pushed down.

- The join must be in a `SELECT` statement.
- `oracle_fdw` must be able to push down all join conditions and `WHERE` clauses.
- Cross joins without join conditions are not pushed down.
- If a join is pushed down, `ORDER BY` clauses will not be pushed down.

It is important that table statistics for both foreign tables have been collected with `ANALYZE` for Postgres Pro to determine the best join strategy.

#### H.1.4.7. Modifying Foreign Data

`oracle_fdw` supports `INSERT`, `UPDATE`, and `DELETE` on foreign tables. This is allowed by default (also in databases upgraded from an earlier Postgres Pro release) and can be disabled by setting the [readonly](#) table option.

For `UPDATE` and `DELETE` to work, the columns corresponding to the primary key columns of the Oracle table must have the [key](#) column option set. These columns are used to identify a foreign table row, so make sure that the option is set on *all* columns that belong to the primary key.

If you omit a foreign table column during `INSERT`, that column is set to the value defined in the `DEFAULT` clause on the Postgres Pro foreign table (or `NULL` if there is no `DEFAULT` clause). `DEFAULT` clauses on the corresponding Oracle columns are not used. If the Postgres Pro foreign table does not include all columns of the Oracle table, the Oracle `DEFAULT` clauses will be used for the columns not included in the foreign table definition.

The `RETURNING` clause on `INSERT`, `UPDATE` and `DELETE` is supported except for columns with Oracle data types `LONG` and `LONG RAW` (Oracle doesn't support these data types in the `RETURNING` clause).

Triggers on foreign tables are supported. Triggers defined with `AFTER` and `FOR EACH ROW` require that the foreign table has no columns with Oracle data type `LONG` or `LONG RAW`. This is because such triggers make use of the `RETURNING` clause mentioned above.

While modifying foreign data works, the performance is not particularly good, specifically when many rows are affected, because (owing to the way foreign data wrappers work) each row has to be treated individually.

Transactions are forwarded to Oracle so `BEGIN`, `COMMIT`, `ROLLBACK`, and `SAVEPOINT` work as expected. Prepared statements involving Oracle are not supported. See the [Internals](#) section for details.

Since `oracle_fdw` uses serialized transactions by default, it is possible that data modifying statements lead to a serialization failure:

```
ORA-08177: can't serialize access for this transaction
```

This can happen if concurrent transactions modify the table and gets more likely in long running transactions. Such errors can be identified by their `SQLSTATE` (40001). An application using `oracle_fdw` should retry transactions that fail with this error.

It is possible to use a different transaction isolation level, see [Foreign Server Options](#) for a discussion.

#### H.1.4.8. EXPLAIN

Postgres Pro's [EXPLAIN](#) will show the query that is actually issued to Oracle. `EXPLAIN VERBOSE` will show Oracle's execution plan (that will not work with Oracle server 9i or older, see [Problems](#)).

#### H.1.4.9. ANALYZE

You can use [ANALYZE](#) to gather statistics on a foreign table. This is supported by `oracle_fdw`.

Without statistics, Postgres Pro has no way to estimate the row count for queries on a foreign table, which can cause bad execution plans to be chosen.

Postgres Pro will *not* automatically gather statistics for foreign tables with the autovacuum daemon like it does for normal tables, so it is particularly important to run `ANALYZE` on foreign tables after creation and whenever the remote table has changed significantly.

Keep in mind that analyzing an Oracle foreign table will result in a full sequential table scan. You can use the table option `sample_percent` to speed this up by using only a sample of the Oracle table.

#### H.1.4.10. PostGIS Support

The data type `geometry` is only available when PostGIS is installed.

The only supported geometry types are `POINT`, `LINE`, `POLYGON`, `MULTIPOINT`, `MULTILINE`, and `MULTIPOLYGON` in two and three dimensions. Empty PostGIS geometries are not supported because they have no equivalent in Oracle Spatial.

NULL values for Oracle `SRID` will be converted to 0 and vice versa. For other conversions between Oracle `SRID` and PostGIS `SRID`, create a file `srid.map` in the Postgres Pro `share` directory. Each line of this file shall contain an Oracle `SRID` and the corresponding PostGIS `SRID`, separated by a whitespace. Keep the file small for good performance.

#### H.1.4.11. Support for `IMPORT FOREIGN SCHEMA`

`IMPORT FOREIGN SCHEMA` is supported to bulk import table definitions for all tables in an Oracle schema. In addition to the documentation of `IMPORT FOREIGN SCHEMA`, consider the following:

- `IMPORT FOREIGN SCHEMA` will create foreign tables for all objects found in `ALL_TAB_COLUMNS`. That includes tables, views and materialized views, but not synonyms.
- These are the supported options for `IMPORT FOREIGN SCHEMA`:
  - `case` controls case folding for table and column names during import.

The possible values are:

- `keep`: leave the names as they are in Oracle, usually in upper case.
- `lower`: translate all table and column names to lower case.
- `smart`: only translate names that are all upper case in Oracle (this is the default).
- `collation` is the collation used for case folding for the `lower` and `smart` options of `case`.

The default value is `default`, which is the database's default collation. Only collations in the `pg_catalog` schema are supported. See the `collname` values in the `pg_collation` catalog for a list of possible values.

- `dblink` is the Oracle database link through which the schema is accessed.

This name must be written exactly as it occurs in Oracle's system catalog so normally consist of uppercase letters only.

- `readonly` sets the `readonly` option on all imported tables.
- `skip_tables` (default `false`): don't import tables.
- `skip_views` (default `false`): don't import views.
- `skip_matviews` (default `false`): don't import materialized views.
- `max_long` sets the `max_long` option on all imported tables.
- `sample_percent` sets the `sample_percent` option on all imported tables.
- `prefetch` sets the `prefetch` option on all imported tables.
- `lob_prefetch` sets the `lob_prefetch` option on all imported tables.
- `nchar` sets the `nchar` option on all imported tables.

- `set_timezone` sets the [set\\_timezone](#) option on all imported tables.
- The Oracle schema name must be written exactly as it is in Oracle, so normally in upper case. Since Postgres Pro translates names to lower case before processing, you must protect the schema name with double quotes (for example, "SCOTT").
- Table names in the `LIMIT TO` or `EXCEPT` clause must be written as they will appear in Postgres Pro after the case folding described above.

Note that `IMPORT FOREIGN SCHEMA` does not work with Oracle server 8i; see the [Problems](#) section for details.

## H.1.5. Reference

### H.1.5.1. Objects Created by the Extension

```
oracle_fdw_handler() RETURNS fdw_handler
oracle_fdw_validator(text[], oid) RETURNS void
```

These functions are the handler and validator functions necessary to create a foreign data wrapper.

```
FOREIGN DATA WRAPPER oracle_fdw
  HANDLER oracle_fdw_handler
  VALIDATOR oracle_fdw_validator
```

The extension automatically creates a foreign data wrapper named `oracle_fdw`. Normally, that's all you need, and you can proceed to define foreign servers. You can create additional Oracle foreign data wrappers, for example, if you need to set the [nls\\_lang](#) option (you can alter the existing `oracle_fdw` wrapper, but all modifications will be lost after a dump/restore).

```
oracle_close_connections() RETURNS void
```

This function can be used to close all open Oracle connections in this session. See [Usage](#) for further description.

```
oracle_diag(name DEFAULT NULL) RETURNS text
```

This function is useful for diagnostic purposes only. It will return the versions of `oracle_fdw`, Postgres Pro server, and Oracle client. If called with no argument or `NULL`, it will additionally return the values of some environment variables used for establishing Oracle connections. If called with the name of a foreign server, it will additionally return the Oracle server version.

```
oracle_execute(server name, stmt text) RETURNS void
```

This function can be used to execute arbitrary SQL statements on the remote Oracle server. That will only work with statements that do not return results (typically DDL statements).

Be careful when using this function since it might disturb the transaction management of `oracle_fdw`. Remember that running a DDL statement in Oracle will issue an implicit `COMMIT`. You are best advised to use this function outside of multi-statement transactions.

### H.1.5.2. Options

#### H.1.5.2.1. Foreign Data Wrapper Options

#### Important

If you modify the default foreign data wrapper `oracle_fdw`, any changes will be lost upon dump/restore. Create a new foreign data wrapper if you want the options to be persistent. The SQL script shipped with the software contains a `CREATE FOREIGN DATA WRAPPER` statement you can use.

[nls\_lang]

Sets the `NLS_LANG` environment variable for Oracle to this value. `NLS_LANG` is in the form *language\_territory.charset* (for example, `AMERICAN_AMERICA.AL32UTF8`). This must match your database encoding. When this value is not set, `oracle_fdw` will automatically do the right thing if it can and issue a warning if it cannot. Set this only if you know what you are doing. See the [Problems](#) section.

#### H.1.5.2.2. Foreign Server Options

dbserver

The Oracle database connection string for the remote database. This can be in any of the forms that Oracle supports as long as your Oracle client is configured accordingly. Set this to an empty string for local (`BEQUEATH`) connections.

[isolation\_level]

The transaction isolation level to use at the Oracle database. The value can be `serializable`, `read_committed`, or `read_only`. The default is `serializable`.

Note that the Oracle table can be queried more than once during a single Postgres Pro statement (for example, during a nested loop join). To make sure that no inconsistencies caused by race conditions with concurrent transactions can occur, the transaction isolation level must guarantee read stability. This is only guaranteed with Oracle's `SERIALIZABLE` or `READ ONLY` isolation levels.

Unfortunately Oracle's implementation of `SERIALIZABLE` is rather bad and causes serialization errors (ORA-08177) in unexpected situations, like inserts into the table. Using `READ COMMITTED` transactions works around this problem, but *there is a risk of inconsistencies*. If you want to use it, check your execution plans if the foreign scan could be executed more than once.

[nchar]

Setting this option to `on` chooses a more expensive character conversion on the Oracle side. This is required if Oracle tables have `NCHAR` or `NVARCHAR2` columns that contain characters that cannot be represented in the Oracle database character set. The default is `off`.

Setting `nchar` to `on` has a noticeable performance impact, and it causes ORA-01461 errors with `UPDATE` statements that set strings over 2000 bytes (or 16383 if you have `MAX_STRING_SIZE = EXTENDED`). This error seems to be an Oracle bug.

[set\_timezone]

Setting this option to `on` sets the Oracle session time zone to the current value of the Postgres Pro parameter `timezone` when the connection to Oracle is made. This is only useful if you plan to use Oracle columns of type `TIMESTAMP WITH LOCAL TIME ZONE` and want to translate them to `timestamp without time zone` in Postgres Pro. The default is `off`.

Note that if you change `timezone` after the Oracle connection has been established, `oracle_fdw` will not change the Oracle session time zone. You can call `oracle_close_connections()` `RETURNS void` in that case so that a new connection is opened the next time you access a foreign table.

If Oracle does not recognize the time zone, connections will fail with an error like “ORA-01882: timezone region not found”.

In that case, either use a different `timezone` or leave the option set to `off` and set the environment variable `ORA_SDTZ` to an appropriate value in the environment of the Postgres Pro server.

#### H.1.5.2.3. User Mapping Options

user

The Oracle user name for the session. Set this to an empty string for *external authentication* if you don't want to store Oracle credentials in the Postgres Pro database (one simple way is to use an *external password store*).

password

The password for the Oracle user.

#### H.1.5.2.4. Foreign Table Options

table

The Oracle table name. This name must be written exactly as it occurs in Oracle's system catalog so normally consist of uppercase letters only.

To define a foreign table based on an arbitrary Oracle query, set this option to the query enclosed in parentheses:

```
OPTIONS (table '(SELECT col FROM tab WHERE val = ''string''))
```

Do not set the [schema](#) option in this case. INSERT, UPDATE, and DELETE will work on foreign tables defined on simple queries; if you want to avoid that (or confusing Oracle error messages for more complicated queries), use the table option [readonly](#).

dblink

The Oracle database link through which the table is accessed. This name must be written exactly as it occurs in Oracle's system catalog so normally consist of uppercase letters only.

[schema]

The table's schema (or owner). Useful to access tables that do not belong to the connecting Oracle user. This name must be written exactly as it occurs in Oracle's system catalog so normally consist of uppercase letters only.

[max\_long]

The maximal length of any LONG, LONG RAW, and XMLTYPE columns in the Oracle table. Possible values are integers between 1 and 1073741823 (the maximal size of a `bytea` in Postgres Pro). This amount of memory will be allocated at least twice so large values will consume a lot of memory. If [max\\_long](#) is less than the length of the longest value retrieved, you will receive the error message “ORA-01406: fetched column value was truncated”. The default is 32767.

[readonly]

INSERT, UPDATE, and DELETE are only allowed on tables where this option is not set to yes/on/true. The default is false.

[sample\_percent]

This option only influences ANALYZE processing and can be useful to ANALYZE very large tables in a reasonable time.

The value must be between 0.000001 and 100 and defines the percentage of Oracle table blocks that will be randomly selected to calculate Postgres Pro table statistics. This is accomplished using the `SAMPLE BLOCK (x)` clause in Oracle. The default is 100.

ANALYZE will fail with ORA-00933 for tables defined with Oracle queries and may fail with ORA-01446 for tables defined with complex Oracle views.

[prefetch]

Sets the number of rows that will be fetched with a single round-trip between Postgres Pro and Oracle during a foreign table scan. The value must be between 1 and 1000, where a value of zero disables prefetching. The default is 50.

Higher values can speed up performance but will use more memory on the Postgres Pro server.

Note that there is no prefetching if the Oracle table contains columns of the type `MDSYS.SDO_GEOMETRY`.

[lob\_prefetch]

Sets the number of bytes that are prefetched for `BLOB`, `CLOB`, and `BFILE` values. LOBs that exceed that size will require additional round trips between Postgres Pro and Oracle so setting this value bigger than the size of your typical LOB will be good for performance. Choosing bigger values for this option can allocate more memory on the server side but will boost performance for large LOBs. The default is 1048576.

#### H.1.5.2.5. Column Options

[key]

If set to `yes/on/true`, the corresponding column on the foreign Oracle table is considered a primary key column. For `UPDATE` and `DELETE` to work, you must set this option on all columns that belong to the table's primary key. The default is `false`.

[strip\_zeros]

If set to `yes/on/true`, ASCII 0 characters will be removed from the string during transfer. Such characters are valid in Oracle but not in Postgres Pro so they will cause an error when read by `oracle_fdw`. This option only makes sense for `character`, `character varying`, and `text` columns. The default is `false`.

### H.1.6. Problems

#### H.1.6.1. Encoding

Characters stored in an Oracle database that cannot be converted to the Postgres Pro database encoding will silently be replaced by replacement characters, typically a normal or inverted question mark, by Oracle. You will get no warning or error messages.

If you use a Postgres Pro database encoding that Oracle does not know (currently these are `EUC_CN`, `EUC_KR`, `LATIN10`, `MULE_INTERNAL`, `WIN874`, and `SQL_ASCII`), non-ASCII characters cannot be translated correctly. You will get a warning in this case, and the characters will be replaced by replacement characters as described above.

You can set the `nls_lang` option of the foreign data wrapper to force a certain Oracle encoding, but the resulting characters will most likely be incorrect and lead to Postgres Pro error messages. This is probably only useful for `SQL_ASCII` encoding if you know what you are doing.

#### H.1.6.2. Limited Functionality in Old Oracle Versions

The definition of the Oracle system catalogs `V$SQL` and `V$SQL_PLAN` has changed with Oracle 10.1. Using `EXPLAIN VERBOSE` with older Oracle server versions will result in errors like:

```
ERROR:  error describing query: OCISmtExecute failed to execute
        remote query for sql_id
DETAIL:  ORA-00904: "LAST_ACTIVE_TIME": invalid identifier
```

There is no plan to fix this, since Oracle 9i has been out of Extended Support since 2010 and the functionality is not essential.

`IMPORT FOREIGN SCHEMA` throws the following error with Oracle server 8i:

```
ERROR:  error importing foreign schema: OCISmtExecute failed to execute
        column query
DETAIL:  ORA-00904: invalid column name
```

This is because the view `ALL_TAB_COLUMNS` lacks the column `CHAR_LENGTH`, which was added in Oracle 9i.

### H.1.6.3. LDAP Libraries

The Oracle client shared library comes with its own LDAP client implementation conforming to [RFC 1823](#) so these functions have the same names as OpenLDAP's. This will lead to a name collision when the Postgres Pro server was configured `--with-ldap`.

The name collision will not be detected because `oracle_fdw` is loaded at runtime, but trouble will happen if anybody calls an LDAP function. Typically, OpenLDAP is loaded first so if Oracle calls an LDAP function (for example, if you use *directory naming* name resolution), the backend will crash. This can lead to messages like the following (seen on Linux) in the Postgres Pro server log:

```
../../../../libraries/libldap/getentry.c:29: ldap_first_entry:  
Assertion `(ld)->ld_options.ldo_valid == 0x2 )' failed.
```

Since Postgres Pro is built `--with-ldap`, it may work as long as you don't use any LDAP client functionality in Oracle. On some platforms, you can force Oracle's client shared library to be loaded before the Postgres Pro server is started (`LD_PRELOAD` on Linux). Then Oracle's LDAP functions should get used. In that case, Oracle may be able to use LDAP functionality, but using LDAP from Postgres Pro will crash the backend.

You cannot use LDAP functionality both in Postgres Pro and in Oracle.

### H.1.6.4. Serialization Errors

In Oracle 11.2 or above, inserting the first row into a newly created Oracle table with `oracle_fdw` will lead to a serialization error.

This is because of an Oracle feature called *deferred segment creation*, which defers allocation of storage space for a new table until the first row is inserted. This causes a serialization failure with serializable transactions.

This is no serious problem; you can work around it by either ignoring that first error or creating the table with `SEGMENT CREATION IMMEDIATE`.

A much nastier problem is that concurrent inserts can sometimes cause serialization errors when an index page is split concurrently with a modifying serializable transaction.

Oracle claims that this is not a bug, and the suggested solution is to retry the transaction that got a serialization error.

### H.1.6.5. Oracle Bugs

This is the list of Oracle bugs that affect or have affected `oracle_fdw` in the past.

Bug 2728408 can cause “ORA-8177 cannot serialize access for this transaction” even if no modification of remote data is attempted. It can occur with Oracle server 8.1.7.4 (install one-off patch 2728408) or Oracle server 9.2 (install Patch Set 9.2.0.4 or better).

Oracle client 21c is known not to work for `CLOB` columns (they appear empty). There is no ultimate proof that that is an Oracle bug, but other versions are working fine.

## H.1.7. Authors

Laurenz Albe, with notable contributions from Vincent Mora of Oslandia and Tatsuro Yamada of the NTT OSS Center.

## H.2. `pg_failover_slots`

`pg_failover_slots` is a Postgres Pro Enterprise extension designed for automatic creation and synchronization of logical replication slots on physical replicas.

Since logical replication slots are only maintained on the primary node, downstream subscribers don't receive any new changes from a newly promoted primary until the slot is created. This is unsafe because

the information that includes which data a subscriber has confirmed receiving and which log data still needs to be retained for the subscriber will have been lost, resulting in an unknown gap in data changes. The `pg_failover_slots` extension makes logical replication slots usable across a physical failover using the following features:

- Copies any missing replication slots from the primary to the standby.
- Removes any slots from the standby that aren't found on the primary.
- Periodically synchronizes the position of slots on the standby based on the primary.
- Ensures that selected standbys receive data before any of the logical slot walsenders can send data to consumers.

## H.2.1. Installation and Configuration

The `pg_failover_slots` extension is provided with Postgres Pro Enterprise as a separate pre-built package `pg-failover-slots-ent-14` (for the detailed installation instructions, see [Chapter 17](#)).

Once you have Postgres Pro Enterprise installed, do the following:

1. Add the `pg_failover_slots` extension to [shared\\_preload\\_libraries](#) on both the primary instance and any standby that is used for high availability (failover or switchover) purposes:

```
shared_preload_libraries = 'pg_failover_slots'
```

2. Configure prerequisite settings as described in [Section H.2.3](#).

## H.2.2. How to Check the Standby Is Ready

The slots are not synchronized to the standby immediately because of consistency reasons. The standby can be too behind logical slots, or too ahead of logical slots on primary when the `pg_failover_slots` module is activated, so the module does verification and only synchronizes slots when it's actually safe.

This, however, brings a need to verify that the slots are synchronized and that the standby is actually ready to be a failover target with consistent logical decoding for all slots. This only needs to be done initially. Once the slots are synchronized for the first time, they will always be consistent as long as the module is active in the cluster.

The check for whether slots are fully synchronized with primary is relatively simple. The slots just need to be present in the [pg\\_replication\\_slots](#) view on standby and have the `active` state set to `false`. The `active` state set to `true` means the slots is currently being initialized.

For example, consider the following `psql` session:

```
# SELECT slot_name, active FROM pg_replication_slots WHERE slot_type = 'logical';
slot_name      | active
-----+-----
regression_slot1 | f
regression_slot2 | f
regression_slot3 | t
```

This means that slots `regression_slot1` and `regression_slot2` are synchronized from primary to standby and `regression_slot3` is still being synchronized. If failover happens at this stage, the `regression_slot3` will be lost.

Now let's wait a little and query again:

```
# SELECT slot_name, active FROM pg_replication_slots WHERE slot_type = 'logical';
slot_name      | active
-----+-----
regression_slot1 | f
regression_slot2 | f
regression_slot3 | f
```

Now all three slots are synchronized and the standby can be used for failover without losing logical decoding state for any of them.

### H.2.3. Prerequisite Settings

The module throws hard errors if the following settings are not adjusted:

- `hot_standby_feedback` should be on
- `primary_slot_name` should be non-empty

These are necessary to connect to the primary so it can send the `xmin` and `catalog_xmin` separately over `hot_standby_feedback`.

### H.2.4. Configuration Options

The module itself must be added to `shared_preload_libraries` on both the primary instance as well as any standby that is used for high availability (failover or switchover) purposes.

The behavior of `pg_failover_slots` is configurable using these configuration options (set in `postgresql.conf`).

`pg_failover_slots.synchronize_slot_names` (text)

This standby option allows setting which logical slots should be synchronized to this physical standby. It's a comma-separated list of slot filters.

A slot filter is defined as `key:value` pair (separated by colon) where `key` can be one of:

- `name` specifies to match exact slot name
- `name_like` specifies to match slot name against SQL `LIKE` expression
- `plugin` specifies to match slot plugin name against the value

The `key` can be omitted and will default to `name` in that case.

For example, `'my_slot_name,plugin:test_decoding'` will synchronize the slot named `my_slot_name` and any slots that use the `test_decoding` plugin.

If this is set to an empty string, no slots will be synchronized to this physical standby.

The default value is `'name_like:%'`, which means all logical replication slots will be synchronized.

`pg_failover_slots.drop_extra_slots` (boolean)

This standby option controls what happens to extra slots on the standby that are not found on the primary using the `pg_failover_slots.synchronize_slot_names` filter. If it's set to `true` (which is the default), they will be dropped, otherwise they will be kept.

`pg_failover_slots.primary_dsn` (string)

A standby option for specifying the connection string to use to connect to the primary when fetching slot information.

If empty (default), then the same connection string as `primary_conninfo` is used.

#### Note

The `primary_conninfo` parameter cannot be used if there is a `password` field in the connection string because it gets obfuscated by Postgres Pro and `pg_failover_slots` can't actually see the password. In this case, `pg_failover_slots.primary_dsn` must be configured.

`pg_failover_slots.standby_slot_names` (text)

This option is typically used in failover configurations to ensure that the failover-candidate streaming physical replica(s) have received and flushed all changes before they ever become visible to any subscribers. That guarantees that a commit cannot vanish on failover to a standby for the consumer of a logical slot.

Replication slots which names are listed in the comma-separated `pg_failover_slots.standby_slot_names` list are treated specially by the walsender on the primary.

Logical replication walsenders will ensure that all local changes are sent and flushed to the replication slots in `pg_failover_slots.standby_slot_names` before the walsender sends those changes for the logical replication slots. Effectively, it provides a synchronous replication barrier between the named list of slots and all the consumers of logically decoded streams from the walsender.

Any replication slot may be listed in `pg_failover_slots.standby_slot_names`; both logical and physical slots work, but it's generally used for physical slots.

Without this safeguard, two anomalies are possible where a commit can be received by a subscriber and then vanish from the provider on failover because the failover candidate hadn't received it yet:

- For 1+ subscribers, the subscriber may have applied the change but the new provider may execute new transactions that conflict with the received change, as it never happened as far as the provider is concerned;

and/or

- For 2+ subscribers, at the time of failover, not all subscribers have applied the change. The subscribers now have inconsistent and irreconcilable states because the subscribers that didn't receive the commit have no way to get it now.

Setting `pg_failover_slots.standby_slot_names` will (by design) cause subscribers to lag behind the provider if the provider's failover-candidate replica(s) are not keeping up. Monitoring is thus essential.

`pg_failover_slots.standby_slots_min_confirmed` (integer)

Controls how many of the `pg_failover_slots.standby_slot_names` have to confirm before sending data through the logical replication slots. Setting `-1` (the default) means to wait for all entries in `pg_failover_slots.standby_slot_names`.

`pg_failover_slots.worker_nap_time` (integer)

Time to sleep (in ms) between two synchronization attempts. Defaults to 60s.

`pg_failover_slots.maintenance_db` (text)

Database name to use when using `primary_conninfo` to connect to the primary server and fetch the replication slots list. Defaults to `postgres`.

## H.3. tds\_fdw

The `tds_fdw` module provides the foreign data wrapper `tds_fdw`, which can connect to databases that use the Tabular Data Stream (TDS) protocol, such as *Sybase* databases and *Microsoft SQL Server*.

This foreign data wrapper requires a library that implements the DB-Library interface, such as FreeTDS. This has been tested with FreeTDS, but not the proprietary implementations of DB-Library.

### H.3.1. Limitations

- Unlike `WHERE` and column pushdowns, which are supported when `match_column_names` is enabled, `JOIN` pushdown or write operations are not supported.

- DML operations `INSERT`, `UPDATE`, and `DELETE` with foreign tables are not supported.

### H.3.2. Installing `tds_fdw`

`tds_fdw` is provided with Postgres Pro Enterprise as a separate pre-built package `tds-fdw` (for the detailed installation instructions, see [Chapter 17](#)).

Install the `tds_fdw` extension using [CREATE EXTENSION](#).

### H.3.3. Configuring `tds_fdw`

#### H.3.3.1. Managing Character Sets/Encoding

Although many newer versions of the TDS protocol will only use USC-2 to communicate with the server, FreeTDS converts the UCS-2 to the client character set of your choice. To set the client character set, you can set `client charset` in `freetds.conf`. See [The `freetds.conf` File](#) and [Localization and TDS 7.0](#) for details.

You may need more configuring in case you get an error like this with Microsoft SQL Server when working with Unicode data:

```
NOTICE: DB-Library notice: Msg #: 4004, Msg state: 1, Msg: Unicode data in a Unicode-only
collation or ntext data cannot be sent to clients using DB-Library (such as ISQL) or ODBC
version 3.7 or earlier., Server: PILLIUM\SQLEXPRESS, Process: , Line: 1, Level: 16
```

```
ERROR: DB-Library error: DB #: 4004, DB Msg: General SQL Server error: Check messages
from the SQL Server, OS #: -1, OS Msg: (null), Level: 16
```

In this case, you may have to manually set `tds` version in `freetds.conf` to 7.0 or higher. See [The `freetds.conf` File](#) and [Choosing a TDS protocol version](#) for details.

#### H.3.3.2. Configuring Encrypted Connections to MSSQL

This needs to be configured at the `freetds.conf`. See [The `freetds.conf` File](#) and under `freetds.conf` settings, look for encryption.

### H.3.4. Usage

To prepare for database access using `tds_fdw`:

1. Create a foreign server object, using [CREATE SERVER](#), to represent each database you want to connect to.
2. Create a user mapping, using [CREATE USER MAPPING](#), for each database user you want to allow to access each foreign server.
3. Create a foreign table, using [CREATE FOREIGN TABLE](#) or [IMPORT FOREIGN SCHEMA](#), for each table you want to access.

#### H.3.4.1. Creating a Foreign Server

To create a foreign server, execute the [CREATE SERVER](#) command providing the following options:

`servername`

The `servername`, address or hostname of the foreign server. This can be a DSN, as specified in `freetds.conf`. See [FreeTDS name lookup](#) for details. You can set this option to a comma-separated list of server names, then each server is tried until the first connection succeeds. This is useful for automatic failover to a secondary server.

Required: Yes

Default: 127.0.0.1

#### port

The port of the foreign server. Instead of providing a port here, it can be specified in `freetds.conf` (if `servername` is a DSN).

Required: No

#### database

The database to connect to for this server

Required: No

#### dbuse

If `dbuse` is 0, `tds_fdw` will connect directly to `database`. If `dbuse` is not 0, `tds_fdw` will connect to the server's default database and then select the database by calling the DB-Library's `dbuse()` function. For Azure, `dbuse` currently needs to be set to 0.

Required: No

Default: 0

#### language

The language to use for messages and the locale to use for date formats. FreeTDS may default to U.S. English on most systems. You can probably also change this in `freetds.conf`. For information related to this for MS SQL Server, see [SET LANGUAGE in MS SQL Server](#). For information related to Sybase ASE, see [Sybase ASE login options](#) and [SET LANGUAGE in Sybase ASE](#).

Required: No

#### character\_set

The client character set to use for the connection if you need to set this for some reason. For TDS protocol versions 7.0+, the connection always uses UCS-2, so this parameter does nothing in those cases. See [Localization and TDS 7.0](#) for details.

Required: No

#### tds\_version

The version of the TDS protocol to use for this server. See [Choosing a TDS protocol version](#) and [History of TDS Versions](#) for details.

Required: No

#### msg\_handler

The function used for the TDS message handler. Can be one of the following values:

- `notice`: TDS messages are turned into PostgreSQL notices
- `blackhole`: TDS messages are ignored

Required: No

Default: `blackhole`

#### fdw\_startup\_cost

A cost that is used in query planning to represent the overhead of using this foreign data wrapper.

Required: No

#### fdw\_tuple\_cost

A cost that is used in query planning to represent the overhead of fetching rows from this server.

Required: No

`sqlserver_ansi_mode`

A cost that is used to represent the overhead of fetching rows from this server used in query planning.

This option is supported for SQL Server only. Setting this to `true` will enable the following server-side settings after a successful connection to the foreign server:

- `CONCAT_NULLS_YIELDS_NULL` ON
- `ANSI_NULLS` ON
- `ANSI_WARNINGS` ON
- `QUOTED_IDENTIFIER` ON
- `ANSI_PADDING` ON
- `ANSI_NULL_DFLT_ON` ON

Those parameters in summary are comparable to the SQL Server option `ANSI_DEFAULTS`. In contrast, `sqlserver_ansi_mode` currently does not activate the following options:

- `CURSOR_CLOSE_ON_COMMIT`
- `IMPLICIT_TRANSACTIONS`

This follows the behavior of the native ODBC and OLEDB driver for SQL servers, which explicitly turn them off if not configured otherwise.

Required: No

Default: `false`

Some foreign table options can also be set at the server level. Those include:

- `use_remote_estimate`
- `row_estimate_method`

### Example H.1. Create a Foreign Server

```
CREATE SERVER mssql_svr
  FOREIGN DATA WRAPPER tds_fdw
  OPTIONS (servername '127.0.0.1', port '1433', database 'tds_fdw_test', tds_version
    '7.1');
```

### H.3.4.2. Creating a User Mapping

To create a user mapping, execute the `CREATE USER MAPPING` command providing the following options:

`username`

The username of the account on the foreign server

#### Important

If you are using Azure SQL, then your username for the foreign server will need to be in the format `username@servername`. If you only use the username, the authentication will fail.

Required: Yes

`password`

The password of the account on the foreign server

Required: Yes

### Example H.2. Create a User Mapping

```
CREATE USER MAPPING FOR postgres
SERVER mssql_svr
OPTIONS (username 'sa', password '');
```

### H.3.4.3. Creating a Foreign Table

To create a foreign table, execute the [CREATE FOREIGN TABLE](#) command providing the following options:

`query`

The query string to use to query the foreign table

Required: Yes (mutually exclusive with `table_name`)

`schema_name`

The schema that the table is in. The schema name can also be included in `table_name`.

Required: No

`table_name`

The table on the foreign server to query

Aliases: *table*

Required: Yes (mutually exclusive with `query`)

`match_column_names`

Match local columns with remote columns by comparing their table names instead of using the order in which they appear in the result set. Required for `WHERE` and column pushdowns.

Required: No

`use_remote_estimate`

Estimate the size of the table by performing some operation on the remote server, as defined by `row_estimate_method`, instead of using the local estimate, as defined by `local_tuple_estimate`

Required: No

`local_tuple_estimate`

A locally set estimate of the number of tuples that is used when `use_remote_estimate` is disabled

Required: No

`row_estimate_method`

Can be one of the following values:

- `execute`: Execute the query on the remote server and get the actual number of rows in the query
- `showplan_all`: Get the estimated number of rows using *MS SQL Server's* `SET SHOWPLAN_ALL`

Required: No

Default: `execute`

### Example H.3. Create a Foreign Table

Using a `table_name` definition:

```
CREATE FOREIGN TABLE mssql_table (  
    id integer,  
    data varchar)  
SERVER mssql_svr  
OPTIONS (table_name 'dbo.mytable', row_estimate_method 'showplan_all');
```

Using a `schema_name` and `table_name` definition:

```
CREATE FOREIGN TABLE mssql_table (  
    id integer,  
    data varchar)  
SERVER mssql_svr  
OPTIONS (schema_name 'dbo', table_name 'mytable', row_estimate_method  
'showplan_all');
```

Using a `query` definition:

```
CREATE FOREIGN TABLE mssql_table (  
    id integer,  
    data varchar)  
SERVER mssql_svr  
OPTIONS (query 'SELECT * FROM dbo.mytable', row_estimate_method 'showplan_all');
```

Setting a remote column name:

```
CREATE FOREIGN TABLE mssql_table (  
    id integer,  
    col2 varchar OPTIONS (column_name 'data'))  
SERVER mssql_svr  
OPTIONS (schema_name 'dbo', table_name 'mytable', row_estimate_method  
'showplan_all');
```

#### H.3.4.4. Importing a Foreign Schema

To import a foreign schema, execute the [IMPORT FOREIGN SCHEMA](#) command providing the following options:

`import_default`

Controls whether column `DEFAULT` expressions are included in the definitions of foreign tables

Required: No

Default: false

`import_not_null`

Controls whether column `NOT NULL` constraints are included in the definitions of foreign tables

Required: No

Default: true

### Example H.4. Import a Foreign Schema

```
IMPORT FOREIGN SCHEMA dbo  
EXCEPT (mssql_table)  
FROM SERVER mssql_svr  
INTO public  
OPTIONS (import_default 'true');
```

### H.3.4.5. Setting Variables

To set a variable, execute the [SET](#) command.

The following variables are available:

`tds_fdw.show_before_row_memory_stats`

Print memory context stats to the Postgres Pro log before each row is fetched

`tds_fdw.show_after_row_memory_stats`

Print memory context stats to the Postgres Pro log after each row is fetched

`tds_fdw.show_finished_memory_stats`

Print memory context stats to the Postgres Pro log when a query is finished

#### Example H.5. Set a Variable

```
postgres=# SET tds_fdw.show_finished_memory_stats=1;
SET
```

### H.3.4.6. Viewing the Query Issued on the Remote System

To view the query issued on the remote system, execute the [EXPLAIN](#) [ `VERBOSE` ] command.

## H.3.5. Author

Geoff Montee

# Appendix I. Additional Supplied Programs

This appendix, [Appendix F](#), and [Appendix G](#) contain information regarding additional modules available in the Postgres Pro Enterprise distribution. See [Appendix F](#) and [Appendix G](#) for more information about the server extensions and plug-ins.

This appendix covers the utility programs. Once installed, they are found in the `bin` directory of the Postgres Pro Enterprise installation and can be used like any other program.

## I.1. Additional PostgreSQL/Postgres Pro Client Applications

This section covers PostgreSQL/Postgres Pro additional client applications included in the Postgres Pro Enterprise distribution. They can be run from anywhere, independent of where the database server resides. See also [Postgres Pro Client Applications](#) for information about client applications that are part of the core Postgres Pro Enterprise distribution.

## oid2name

oid2name — resolve OIDs and file nodes in a Postgres Pro data directory

## Synopsis

```
oid2name [option...]
```

## Description

oid2name is a utility program that helps administrators to examine the file structure used by Postgres Pro. To make use of it, you need to be familiar with the database file structure, which is described in [Chapter 70](#).

### Note

The name “oid2name” is historical, and is actually rather misleading, since most of the time when you use it, you will really be concerned with tables' filenode numbers (which are the file names visible in the database directories). Be sure you understand the difference between table OIDs and table filenodes!

oid2name connects to a target database and extracts OID, filenode, and/or table name information. You can also have it show database OIDs or tablespace OIDs.

## Options

oid2name accepts the following command-line arguments:

```
-f filenode
```

```
--filenode=filenode
```

show info for table with filenode *filenode*.

```
-i
```

```
--indexes
```

include indexes and sequences in the listing.

```
-o oid
```

```
--oid=oid
```

show info for table with OID *oid*.

```
-q
```

```
--quiet
```

omit headers (useful for scripting).

```
-s
```

```
--tablespaces
```

show tablespace OIDs.

```
-S
```

```
--system-objects
```

include system objects (those in `information_schema`, `pg_toast` and `pg_catalog` schemas).

```
-t tablename_pattern
```

```
--table=tablename_pattern
```

show info for table(s) matching *tablename\_pattern*.

`-V`  
`--version`  
Print the oid2name version and exit.

`-x`  
`--extended`  
display more information about each object shown: tablespace name, schema name, and OID.

`-?`  
`--help`  
Show help about oid2name command line arguments, and exit.

oid2name also accepts the following command-line arguments for connection parameters:

`-d database`  
`--dbname=database`  
database to connect to.

`-h host`  
`--host=host`  
database server's host.

`-H host`  
database server's host. Use of this parameter is *deprecated* as of Postgres Pro 12.

`-p port`  
`--port=port`  
database server's port.

`-U username`  
`--username=username`  
user name to connect as.

To display specific tables, select which tables to show by using `-o`, `-f` and/or `-t`. `-o` takes an OID, `-f` takes a filenode, and `-t` takes a table name (actually, it's a `LIKE` pattern, so you can use things like `foo%`). You can use as many of these options as you like, and the listing will include all objects matched by any of the options. But note that these options can only show objects in the database given by `-d`.

If you don't give any of `-o`, `-f` or `-t`, but do give `-d`, it will list all tables in the database named by `-d`. In this mode, the `-s` and `-i` options control what gets listed.

If you don't give `-d` either, it will show a listing of database OIDs. Alternatively you can give `-s` to get a tablespace listing.

## Environment

`PGHOST`  
`PGPORT`  
`PGUSER`

Default connection parameters.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 36.15](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

oid2name requires a running database server with non-corrupt system catalogs. It is therefore of only limited use for recovering from catastrophic database corruption situations.

## Examples

```
$ # what's in this database server, anyway?
$ oid2name
All databases:
  Oid  Database Name  Tablespace
-----
 17228      alvherre  pg_default
 17255      regression pg_default
 17227      template0  pg_default
    1      template1  pg_default

$ oid2name -s
All tablespaces:
  Oid  Tablespace Name
-----
 1663      pg_default
 1664      pg_global
155151      fastdisk
155152      bigdisk

$ # OK, let's look into database alvherre
$ cd $PGDATA/base/17228

$ # get top 10 db objects in the default tablespace, ordered by size
$ ls -lS * | head -10

```

### Description

pg\_probackup is a utility to manage backup and recovery of Postgres Pro database clusters. It is designed to perform periodic backups of the PostgreSQL instance that enable you to restore the server in case of a failure. pg\_probackup supports PostgreSQL 11 or higher. In Postgres Pro Enterprise, pg\_probackup provides S3 (Simple Storage Service) support for storing data in private clouds.

#### Note

pg\_probackup provides complete processing of S3 interface logging.

- [Overview](#)
- [Quick Start](#)
- [Installation and Setup](#)
- [Command-Line Reference](#)
- [Usage](#)

## Overview

As compared to other backup solutions, `pg_probackup` offers the following benefits that can help you implement different backup strategies and deal with large amounts of data:

- S3 support for storing data in private clouds using MinIO object storage, Amazon S3 storage, and VK Cloud storage: provided in Postgres Pro Enterprise. Backup data is transferred to and from S3 without saving it in intermediate locations thus eliminating the need of having a large temporary storage.
- Incremental backup: with three different incremental modes, you can plan the backup strategy in accordance with your data flow. Incremental backups allow you to save disk space and speed up backup as compared to taking full backups. It is also faster to restore the cluster by applying incremental backups than by replaying WAL files.
- Incremental restore: speed up restore from a backup by reusing valid unchanged pages available in PGDATA.
- CFS (Compressed File System) support for incremental backups in `DELTA`, `PAGE`, and `PTRACK` (the fastest) modes: provided in Postgres Pro Enterprise.
- Validation: automatic data consistency checks and on-demand backup validation without actual data recovery.
- Verification: on-demand verification of Postgres Pro instance with the `checkdb` command.
- Retention: managing WAL archive and backups in accordance with retention policy. You can configure retention policy based on recovery time or the number of backups to keep, as well as specify time to live (TTL) for a particular backup. Expired backups can be merged or deleted.
- Parallelization: running `backup`, `restore`, `merge`, `delete`, `validate`, and `checkdb` processes on multiple parallel threads.
- Compression: storing backup data in a compressed state to save disk space.
- Deduplication: saving disk space by excluding non-data files (such as `_vm` or `_fsm`) from incremental backups if these files have not changed since they were copied into one of the previous backups in this incremental chain.
- Remote operations: backing up Postgres Pro instance located on a remote system or restoring a backup remotely.
- Backups from a standby: avoiding extra load on the primary by taking backups from a standby server.
- External directories: backing up files and directories located outside of the Postgres Pro data directory (PGDATA), such as scripts, configuration files, logs, or SQL dump files.
- Backup catalog: getting the list of backups and the corresponding meta information in plain text or JSON formats.
- Archive catalog: getting the list of all WAL timelines and the corresponding meta information in plain text or JSON formats.
- Partial restore: restoring only the specified databases.
- Catchup: cloning a Postgres Pro instance for a fallen-behind standby server to “catch up” with the primary.

To manage backup data, `pg_probackup` creates a *backup catalog*. This is a directory that stores all backup files with additional meta information, as well as WAL archives required for point-in-time recovery. You can store backups for different instances in separate subdirectories of a single backup catalog.

Using `pg_probackup`, you can take full or incremental [backups](#):

- FULL backups contain all the data files required to restore the database cluster.
- Incremental backups operate at the page level, only storing the data that has changed since the previous backup. It allows you to save disk space and speed up the backup process as compared to

taking full backups. It is also faster to restore the cluster by applying incremental backups than by replaying WAL files. `pg_probackup` supports the following modes of incremental backups:

- **DELTA backup.** In this mode, `pg_probackup` reads all data files in the data directory and copies only those pages that have changed since the previous backup. This mode can impose read-only I/O pressure equal to a full backup.
- **PAGE backup.** In this mode, `pg_probackup` scans all WAL files in the archive from the moment the previous full or incremental backup was taken. Newly created backups contain only the pages that were mentioned in WAL records. This requires all the WAL files since the previous backup to be present in the WAL archive. If the size of these files is comparable to the total size of the database cluster files, speedup is smaller, but the backup still takes less space. You have to configure WAL archiving as explained in [Setting up continuous WAL archiving](#) to make PAGE backups.
- **PTRACK backup.** In this mode, Postgres Pro tracks page changes on the fly. Continuous archiving is not necessary for it to operate. Each time a relation page is updated, this page is marked in a special PTRACK bitmap. Tracking implies some minor overhead on the database server operation, but speeds up incremental backups significantly.

### Warning

After promoting a standby server to primary and switching [timelines](#), take the first backup in **either FULL or DELTA mode**. Using other backup modes in this case may result in data corruption.

`pg_probackup` can take only physical online backups, and online backups require WAL for consistent recovery. So regardless of the chosen backup mode (FULL, PAGE or DELTA), any backup taken with `pg_probackup` must use one of the following *WAL delivery modes*:

- **ARCHIVE.** Such backups rely on [continuous archiving](#) to ensure consistent recovery. This is the default WAL delivery mode.
- **STREAM.** Such backups include all the files required to restore the cluster to a consistent state at the time the backup was taken. Regardless of [continuous archiving](#) having been set up or not, the WAL segments required for consistent recovery are streamed via replication protocol during backup and included into the backup files. That's why such backups are called *autonomous*, or *stand-alone*.

### Limitations

`pg_probackup` currently has the following limitations:

- The remote mode is not supported on Windows systems.
- On Unix systems, for Postgres Pro, a backup can be made only by the same OS user that has started the Postgres Pro server. For example, if Postgres Pro server is started by user `postgres`, the `backup` command must also be run by user `postgres`. To satisfy this requirement when taking backups in the [remote mode](#) using SSH, you must set `--remote-user` option to `postgres`.
- The Postgres Pro server from which the backup was taken and the restored server must be compatible by the [block\\_size](#) and [wal\\_block\\_size](#) parameters and have the same major release number. Depending on cluster configuration, Postgres Pro itself may apply additional restrictions, such as CPU architecture or libc/icu versions.
- Special limitations of `pg_probackup` in Postgres Pro Enterprise:
  - Incremental backup and restore for CFS tablespaces require `ptrack` 2.4.0 or higher.
  - Only the following commands can be launched in the remote mode: [add-instance](#), [backup](#), [restore](#), [delete](#), [catchup](#), [archive-push](#), and [archive-get](#).

### Quick Start

To quickly get started with `pg_probackup`, complete the steps below. This will set up FULL and DELTA backups in the remote mode and demonstrate some basic `pg_probackup` operations. In the following, these terms are used:

- backup — Postgres Pro role used to connect to the Postgres Pro cluster.
- backupdb — database used to connect to the Postgres Pro cluster.
- backup\_host — host with the backup catalog.
- backup\_user — user on backup\_host running all pg\_probackup operations.
- /mnt/backups — directory on backup\_host where the backup catalog is stored.
- postgres\_host — host with the Postgres Pro cluster.
- postgres — user on postgres\_host under which Postgres Pro cluster processes are running.
- /var/lib/pgpro/std-16/data — Postgres Pro data directory on postgres\_host.

**Steps to perform:**

1. Install pg\_probackup on both backup\_host and postgres\_host.
2. [Set up an SSH connection](#) from backup\_host to postgres\_host.
3. [Configure](#) your database cluster for [STREAM backups](#).
4. Initialize the backup catalog:

```
backup_user@backup_host:~$ pg_probackup init -B /mnt/backups
INFO: Backup catalog '/mnt/backups' successfully initialized
```

5. Add a backup instance called mydb to the backup catalog:

```
backup_user@backup_host:~$ pg_probackup add-instance \
-B /mnt/backups \
-D /var/lib/pgpro/std-16/data \
--instance=node \
--remote-host=postgres_host \
--remote-user=postgres
INFO: Instance 'node' successfully initialized
```

6. Make a FULL backup:

```
backup_user@backup_host:~$ pg_probackup backup \
-B /mnt/backups \
-b FULL \
--instance=node \
--stream \
--compress-algorithm=zstd \
--remote-host=postgres_host \
--remote-user=postgres \
-U backup \
-d backupdb
INFO: Backup start, pg_probackup version: 2.7.3, instance: node, backup ID: SBOL6J,
backup mode: FULL, wal mode: STREAM, remote: true, compress-algorithm: zstd,
compress-level: 1
WARNING: pgpro_edition() function is old-style and will be removed in future major
release, use pgpro_edition GUC variable instead.
INFO: This PostgreSQL instance was initialized with data block checksums. Data
block corruption will be detected
INFO: Database backup start
INFO: wait for pg_backup_start()
INFO: PGDATA size: 96MB
INFO: Current Start LSN: 0/8000028, TLI: 1
INFO: Start transferring data files
INFO: Data files are transferred, time elapsed: 2s
INFO: wait for pg_stop_backup()
INFO: pg_stop_backup() successfully executed
INFO: stop_stream_lsn 0/9000000 currentpos 0/9000000
INFO: backup->stop_lsn 0/8004E40
INFO: Getting the Recovery Time from WAL
```

```
INFO: Syncing backup files to disk
INFO: Backup files are synced, time elapsed: 1s
INFO: Validating backup SBOL6J
INFO: Backup SBOL6J data files are valid
INFO: Backup SBOL6J resident size: 53MB
INFO: Backup SBOL6J completed
```

## 7. List the backups of the instance:

```
backup_user@backup_host:~$ pg_probackup show \
-B /mnt/backups \
--instance=node
```

```
=====
Instance  Version  ID          Recovery Time          Mode  WAL Mode  TLI
Time Data   WAL  Zalg  Zratio  Start LSN  Stop LSN  Status
=====
node      17      SBOL6J  2024-04-09 18:18:21.970314+03  FULL  STREAM    1/0
4s 37MB 16MB  zstd  2.57  0/8000028 0/8004E40  OK
=====
```

## 8. Make an incremental backup in the DELTA mode:

```
backup_user@backup_host:~$ pg_probackup backup \
-B /mnt/backups \
-b DELTA \
--instance=node \
--stream \
--compress-algorithm=zstd \
--remote-host=postgres_host \
--remote-user=postgres \
-U backup \
-d backupdb
```

```
INFO: Backup start, pg_probackup version: 2.7.3, instance: node, backup ID: SBOL6N,
backup mode: DELTA, wal mode: STREAM, remote: true, compress-algorithm: zstd,
compress-level: 1
WARNING: pgpro_edition() function is old-style and will be removed in future major
release, use pgpro_edition GUC variable instead.
INFO: This PostgreSQL instance was initialized with data block checksums. Data
block corruption will be detected
INFO: Database backup start
INFO: wait for pg_backup_start()
INFO: Parent backup: SBOL6J
INFO: PGDATA size: 96MB
INFO: Current Start LSN: 0/9000028, TLI: 1
INFO: Parent Start LSN: 0/8000028, TLI: 1
INFO: Start transferring data files
INFO: Data files are transferred, time elapsed: 1s
INFO: wait for pg_stop_backup()
INFO: pg_stop_backup() successfully executed
INFO: stop_stream_lsn 0/A000000 currentpos 0/A000000
INFO: backup->stop_lsn 0/9000190
INFO: Getting the Recovery Time from WAL
INFO: Syncing backup files to disk
INFO: Backup files are synced, time elapsed: 0
INFO: Validating backup SBOL6N
INFO: Backup SBOL6N data files are valid
INFO: Backup SBOL6N resident size: 17MB
INFO: Backup SBOL6N completed
```

## 9. Add or modify some parameters in the pg\_probackup configuration file, so that you do not have to specify them each time on the command line:

```
backup_user@backup_host:~$ pg_probackup set-config \  
-B /mnt/backups \  
--instance=node \  
--remote-host=postgres_host \  
--remote-user=postgres \  
-U backup \  
-d backupdb
```

#### 10. Check the configuration of the instance:

```
backup_user@backup_host:~$ pg_probackup show-config \  
-B /mnt/backups \  
--instance=node  
# Backup instance information  
pgdata = /var/lib/pgpro/std-16/data  
system-identifier = 7355886958826772732  
xlog-seg-size = 16777216  
# Connection parameters  
pgdatabase = backupdb  
pghost = postgres_host  
pguser = backup  
# Archive parameters  
archive-timeout = 5min  
# Logging parameters  
log-level-console = INFO  
log-level-file = OFF  
log-format-console = PLAIN  
log-format-file = PLAIN  
log-filename = pg_probackup.log  
log-rotation-size = 0TB  
log-rotation-age = 0d  
# Retention parameters  
retention-redundancy = 0  
retention-window = 0  
wal-depth = 0  
# Compression parameters  
compress-algorithm = none  
compress-level = 1  
# Remote access parameters  
remote-proto = ssh  
remote-host = postgres_host  
remote-user = postgres
```

Note that the parameters not modified via `set-config` retain their default values.

#### 11. Make another incremental backup in the DELTA mode, omitting the parameters stored in the configuration file earlier:

```
backup_user@backup_host:~$ pg_probackup backup \  
-B /mnt/backups \  
-b DELTA \  
--instance=node \  
--stream \  
--compress-algorithm=zstd  
INFO: Backup start, pg_probackup version: 2.7.3, instance: node, backup ID: SBOL6P,  
backup mode: DELTA, wal mode: STREAM, remote: true, compress-algorithm: zstd,  
compress-level: 1  
WARNING: pgpro_edition() function is old-style and will be removed in future major  
release, use pgpro_edition GUC variable instead.
```

```
INFO: This PostgreSQL instance was initialized with data block checksums. Data
      block corruption will be detected
INFO: Database backup start
INFO: wait for pg_backup_start()
INFO: Parent backup: SBOL6N
INFO: PGDATA size: 96MB
INFO: Current Start LSN: 0/A000028, TLI: 1
INFO: Parent Start LSN: 0/9000028, TLI: 1
INFO: Start transferring data files
INFO: Data files are transferred, time elapsed: 1s
INFO: wait for pg_stop_backup()
INFO: pg_stop_backup() successfully executed
INFO: stop_stream_lsn 0/B000000 currentpos 0/B000000
INFO: backup->stop_lsn 0/A000190
INFO: Getting the Recovery Time from WAL
INFO: Syncing backup files to disk
INFO: Backup files are synced, time elapsed: 0
INFO: Validating backup SBOL6P
INFO: Backup SBOL6P data files are valid
INFO: Backup SBOL6P resident size: 17MB
INFO: Backup SBOL6P completed
```

## 12. List the backups of the instance again:

```
backup_user@backup_host:~$ pg_probackup show \
    -B /mnt/backups \
    --instance=node
```

```
=====
Instance  Version  ID      Recovery Time      Mode  WAL Mode  TLI
Time      Data    WAL    Zalg   Zratio  Start LSN  Stop LSN  Status
=====
```

|      |        |      |        |                               |           |           |     |
|------|--------|------|--------|-------------------------------|-----------|-----------|-----|
| node | 17     |      | SBOL6P | 2024-04-09 18:18:26.630175+03 | DELTA     | STREAM    | 1/1 |

INFO: Syncing restored files to disk
```

```
INFO: Restored backup files are synced, time elapsed: 1s
INFO: Restore of backup SBOL6P completed.
```

## Installation and Setup

Once you have `pg_probackup` installed, complete the following setup:

- Initialize the backup catalog.
- Add a new backup instance to the backup catalog.
- Configure the database cluster to enable `pg_probackup` backups.
- Optionally, configure SSH for running `pg_probackup` operations in the remote mode.
- Optionally, configure S3 for running `pg_probackup` connected to the S3 storage.

### Initializing the Backup Catalog

`pg_probackup` stores all WAL and backup files in the corresponding subdirectories of the backup catalog.

To initialize the backup catalog, run the following command:

```
pg_probackup init -B backup_dir
```

where *backup\_dir* is the path to the backup catalog. If the *backup\_dir* already exists, it must be empty. Otherwise, `pg_probackup` returns an error.

The user launching `pg_probackup` must have full access to the *backup\_dir* directory.

`pg_probackup` creates the *backup\_dir* backup catalog, with the following subdirectories:

- `wal/` — directory for WAL files.
- `backups/` — directory for backup files.

Once the backup catalog is initialized, you can add a new backup instance.

### Adding a New Backup Instance

`pg_probackup` can store backups for multiple database clusters in a single backup catalog. To set up the required subdirectories, you must add a backup instance to the backup catalog for each database cluster you are going to back up.

To add a new backup instance, run the following command:

```
pg_probackup add-instance -B backup_dir -D data_dir --instance=instance_name
[remote_options]
```

Where:

- *data\_dir* is the data directory of the cluster you are going to back up. To set up and use `pg_probackup`, write access to this directory is required.
- *instance\_name* is the name of the subdirectories that will store WAL and backup files for this cluster.
- [remote\\_options](#) are optional parameters that need to be specified only if *data\_dir* is located on a remote system.

`pg_probackup` creates the *instance\_name* subdirectories under the `backups/` and `wal/` directories of the backup catalog. The `backups/instance_name` directory contains the `pg_probackup.conf` configuration file that controls `pg_probackup` settings for this backup instance. If you run this command with the [remote\\_options](#), the specified parameters will be added to `pg_probackup.conf`.

For details on how to fine-tune `pg_probackup` configuration, see [the section called “Configuring pg\\_probackup”](#).

The user launching `pg_probackup` must have full access to *backup\_dir* directory and at least read-only access to *data\_dir* directory. If you specify the path to the backup catalog in the `BACKUP_PATH` environment variable, you can omit the corresponding option when running `pg_probackup` commands.

## Note

For Postgres Pro 11 or higher, it is recommended to use the [group access](#) feature, so that backups can be done by any OS user in the same group as the cluster owner. In this case, the user should have read permissions for the cluster directory.

### Configuring the Database Cluster

Although `pg_probackup` can be used by a superuser, it is recommended to create a separate role with the minimum permissions required for the chosen backup strategy. In these configuration instructions, the `backup` role is used as an example.

For security reasons, it is recommended to run the configuration SQL queries below in a separate database.

```
postgres=# CREATE DATABASE backupdb;
postgres=# \c backupdb
```

To perform a [backup](#), the following permissions for role `backup` are required only in the database **used for connection** to the Postgres Pro server.

For Postgres Pro versions 11 — 14:

```
BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup(boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_wal() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_wal_replay_lsn() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;
COMMIT;
```

For Postgres Pro 15 or higher:

```
BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_backup_start(text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_backup_stop(boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_wal() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_wal_replay_lsn() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;
COMMIT;
```

In the [pg\\_hba.conf](#) file, allow connection to the database cluster on behalf of the `backup` role.

Since `pg_probackup` needs to read cluster files directly, `pg_probackup` must be started by (or connected to, if used in the remote mode) the OS user that has read access to all files and directories inside the data directory (`PGDATA`) you are going to back up.

Depending on whether you plan to take [standalone](#) or [archive](#) backups, Postgres Pro cluster configuration will differ, as specified in the sections below. To back up the database cluster from a standby server, run `pg_probackup` in the remote mode, or create PTRACK backups, additional setup is required.

For details, see the sections [Setting up STREAM Backups](#), [Setting up continuous WAL archiving](#), [Setting up Backup from Standby](#), [Configuring the Remote Mode](#), [Setting up Partial Restore](#), and [Setting up PTRACK Backups](#).

## Setting up STREAM Backups

To set up the cluster for [STREAM](#) backups, complete the following steps:

- If the `backup` role does not exist, create it with the `REPLICATION` privilege when [Configuring the Database Cluster](#):

```
CREATE ROLE backup WITH LOGIN REPLICATION;
```

- If the `backup` role already exists, grant it with the `REPLICATION` privilege:

```
ALTER ROLE backup WITH REPLICATION;
```

- In the `pg_hba.conf` file, allow replication on behalf of the `backup` role.
- Make sure the parameter `max_wal_senders` is set high enough to leave at least one session available for the backup process.
- Set the parameter `wal_level` to be higher than `minimal`.

If you are planning to take PAGE backups in the STREAM mode or perform PITR with STREAM backups, you still have to configure WAL archiving, as explained in the section [Setting up continuous WAL archiving](#).

Once these steps are complete, you can start taking FULL, PAGE, DELTA, and PTRACK backups in the [STREAM](#) WAL mode.

### Note

If you are planning to rely on `.pgpass` for authentication when running backup in STREAM mode, then `.pgpass` must contain credentials for `replication` database, used to establish connection via replication protocol. Example: `pghost:5432:replication:backup_user:my_strong_password`

## Setting up Continuous WAL Archiving

Making backups in the PAGE backup mode, performing [PITR](#) and making backups with the [ARCHIVE](#) WAL delivery mode require [continuous WAL archiving](#) to be enabled. To set up continuous archiving in the cluster, complete the following steps:

- Make sure the `wal_level` parameter is higher than `minimal`.
- If you are configuring archiving on the primary, `archive_mode` must be set to `on` or `always`. To perform archiving on a standby, set this parameter to `always`.
- Set the `archive_command` parameter, as follows:

```
archive_command = '"install_dir/pg_probackup" archive-push -B "backup_dir" --  
instance=instance_name --wal-file-name=%f [remote_options]'
```

where `install_dir` is the installation directory of the `pg_probackup` version you are going to use, `backup_dir` and `instance_name` refer to the already initialized backup catalog instance for this database cluster, and `remote_options` only need to be specified to archive WAL on a remote host. For details about all possible `archive-push` parameters, see the section [archive-push](#).

Once these steps are complete, you can start making backups in the [ARCHIVE](#) WAL mode, backups in the [PAGE](#) backup mode, as well as perform [PITR](#).

You can view the current state of the WAL archive using the [show](#) command. For details, see [the section called “Viewing WAL Archive Information”](#).

If you are planning to make [PAGE](#) backups and/or backups with [ARCHIVE](#) WAL mode from a standby server that generates a small amount of WAL traffic, without long waiting for WAL segment to fill up, consider setting the [archive\\_timeout](#) Postgres Pro parameter **on the primary**. The value of this parameter should be slightly lower than the `--archive-timeout` setting (5 minutes by default), so that there is enough time for the rotated segment to be streamed to a standby and sent to WAL archive before the backup is aborted because of `--archive-timeout`.

### Note

Instead of using the [archive-push](#) command provided by `pg_probackup`, you can use any other tool to set up continuous archiving as long as it delivers WAL segments into `backup_dir/wal/instance_name` directory. If compression is used, it should be `gzip`, and `.gz` suffix in filename is mandatory.

### Note

Instead of configuring continuous archiving by setting the `archive_mode` and `archive_command` parameters, you can opt for using the [pg\\_receivewal](#) utility. In this case, `pg_receivewal -D directory` option should point to `backup_dir/wal/instance_name` directory. `pg_probackup` supports WAL compression that can be done by `pg_receivewal`. “Zero Data Loss” archive strategy can be achieved only by using `pg_receivewal`.

## Setting up Backups from a Standby

`pg_probackup` can take backups from a standby server. This requires the following additional setup:

- On the standby server, set the [hot\\_standby](#) parameter to `on`.
- On the primary server, set the [full\\_page\\_writes](#) parameter to `on`.
- To perform standalone backups on a standby, complete all the steps in section [Setting up STREAM Backups](#).
- To perform archive backups on a standby, complete all steps in section [Setting up continuous WAL archiving](#).

Once these steps are complete, you can start taking FULL, PAGE, DELTA, or PTRACK backups with appropriate WAL delivery mode: ARCHIVE or STREAM, from the standby server.

Backups from a standby server have the following limitations:

- If a standby is promoted to a primary during the backup process, the backup fails.
- All WAL records required for the backup must contain sufficient full-page writes. This requires you to enable `full_page_writes` on the primary, and not to use tools like `pg_compresslog` as [archive\\_command](#) to remove full-page writes from WAL files.

## Setting up Cluster Verification

Logical verification of a database cluster requires the following additional setup. Role `backup` is used as an example:

- Install the [amcheck](#) or [amcheck\\_next](#) extension **in every database** of the cluster:

```
CREATE EXTENSION amcheck;
```

- Grant the following permissions to the `backup` role **in every database** of the cluster:

```
GRANT SELECT ON TABLE pg_catalog.pg_am TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_class TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_database TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_namespace TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_extension TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass) TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass, bool) TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass, bool, bool) TO backup;
```

## Setting up Partial Restore

If you are planning to use partial restore, complete the following additional step:

- Grant the read-only access to `pg_catalog.pg_database` to the backup role only in the database **used for connection** to Postgres Pro server:

```
GRANT SELECT ON TABLE pg_catalog.pg_database TO backup;
```

## Configuring the Remote Mode

`pg_probackup` supports the remote mode that allows you to perform backup, restore and WAL archiving operations remotely. In this mode, the backup catalog is stored on a local system, while Postgres Pro instance to backup and/or to restore is located on a remote system. Currently the only supported remote protocol is SSH.

### Set up SSH

If you are going to use `pg_probackup` in remote mode via SSH, complete the following steps:

1. Install `pg_probackup` on both systems: `backup_host` and `postgres_host`.
2. For communication between the hosts set up a passwordless SSH connection between the `backup_user` user on `backup_host` and the `postgres` user on `postgres_host`:

```
backup_user@backup_host:~$ ssh-copy-id postgres@postgres_host
```

Where:

- `backup_host` is the system with *backup catalog*.
  - `postgres_host` is the system with the Postgres Pro cluster.
  - `backup_user` is the OS user on `backup_host` used to run `pg_probackup`.
  - `postgres` is the user on `postgres_host` under which Postgres Pro cluster processes are running. For Postgres Pro 11 or higher a more secure approach can be used thanks to [group access](#) feature.
3. If you are going to rely on [continuous WAL archiving](#), set up a passwordless SSH connection between the `postgres` user on `postgres_host` and the `backup` user on `backup_host`:

```
postgres@postgres_host:~$ ssh-copy-id backup_user@backup_host
```

4. Make sure `pg_probackup` on `postgres_host` can be located when a connection via SSH is made. For example, for Bash, you can modify `PATH` in `~/.bashrc` of the `postgres` user (above the line in `bashrc` that exits the script for non-interactive shells). Alternatively, for `pg_probackup` commands, specify the path to the directory containing the `pg_probackup` binary on `postgres_host` via the [--remote-path](#) option.

`pg_probackup` in the remote mode via SSH works as follows:

- Only the following commands can be launched in the remote mode: [add-instance](#), [backup](#), [restore](#), [delete](#), [catchup](#), [archive-push](#), and [archive-get](#).
- Operating in remote mode requires `pg_probackup` binary to be installed on both local and remote systems. The versions of local and remote binary must be the same.
- When started in the remote mode, the main `pg_probackup` process on the local system connects to the remote system via SSH and launches one or more agent processes on the remote system, which are called *remote agents*. The number of remote agents is equal to the `-j/--threads` setting.

- The main `pg_probackup` process uses remote agents to access remote files and transfer data between local and remote systems.
- Remote agents try to minimize the network traffic and the number of round-trips between hosts.
- The main process is usually started on `backup_host` and connects to `postgres_host`, but in case of `archive-push` and `archive-get` commands the main process is started on `postgres_host` and connects to `backup_host`.
- Once data transfer is complete, remote agents are terminated and SSH connections are closed.
- If an error condition is encountered by a remote agent, then all agents are terminated and error details are reported by the main `pg_probackup` process, which exits with an error.
- Compression is always done on `postgres_host`, while decompression is always done on `backup_host`.

### Note

You can impose [additional restrictions](#) on SSH settings to protect the system in the event of account compromise.

### Note

Setting the number of threads (`-j/--threads` option) to a value greater than 10 for `pg_probackup` working in the remote mode via SSH may result in the actual number of SSH connections exceeding the maximum allowed number of simultaneous SSH connections on the remote server and consequently lead to an “ERROR: Agent error: `kex_exchange_identification: Connection closed by remote host`” error. To correct the error, either reduce the number of `pg_probackup` threads or adjust the value of `MaxStartups` configuration parameter of the remote SSH server. If SSH is set up as a `xinetd` service on the remote server, adjust the value of the `xinetd` `per_source` configuration parameter rather than `MaxStartups`.

## Configuring S3 Connectivity

`pg_probackup` supports S3 interface for storing backups. Backup data is transferred to and from S3 without saving it in intermediate locations thus eliminating the need of having a large temporary storage.

An example configuration with a remote agent and a cloud storage (S3) is shown in [Figure I.1](#).

**Figure I.1. `pg_probackup` setup with a remote agent and S3**

In this figure, the following logical components are shown:

**Backup server**

A server where the main process of `pg_probackup` runs and where local backups are stored.

**Database server**

A server with a database instance that needs to be backed up or restored.

**Remote agent**

A secondary `pg_probackup` process running on the database server. Only applicable to the remote mode.

**Cloud storage**

A cloud storage for backups.

**Set up Access to S3 Storage**

If you are going to use `pg_probackup` with S3 interface, complete the following steps:

- Create a bucket with a unique and meaningful name in the S3 storage for you future backups.
- Create `ACCESS_KEY` and `SECRET_ACCESS_KEY` tokens to be used for secure connectivity instead of your username and password.
- For communication between `pg_probackup` and S3 server, set values of environment variables corresponding to your S3 server. For example:

```
export PG_PROBACKUP_S3_HOST=127.0.0.1
export PG_PROBACKUP_S3_PORT=9000
export PG_PROBACKUP_S3_REGION=ru-msk
export PG_PROBACKUP_S3_BUCKET_NAME=test1
export PG_PROBACKUP_S3_ACCESS_KEY=admin
export PG_PROBACKUP_S3_SECRET_ACCESS_KEY=password
export PG_PROBACKUP_S3_HTTPS=ON
```

Alternatively, you can provide S3 server settings in the S3 configuration file (see the `--s3-config-file` option in the section [S3 Options](#) for details).

It makes sense to specify S3 server settings if `--s3=minio`, as described in the section [S3 Options](#).

The following environment variables can be specified:

`PG_PROBACKUP_S3_HOST`

Address or list of addresses of the S3 server. A list of one or several semicolon-delimited addresses. Do not add a semicolon after the last address in the list. Each address can include the port number, separated by a colon. If the port number is not specified, the value of `PG_PROBACKUP_S3_PORT` is assumed. Do not add a colon if the port number is not specified.

For example:

```
export PG_PROBACKUP_S3_PORT=80
export PG_PROBACKUP_S3_HOST="127.0.0.1:9000;10.4.13.56:443;172.17.0.1"
```

In this example, for the “127.0.0.1” address, the port 9000 is explicitly specified, for “10.4.13.56”, the port 443 is specified, while for the “172.17.0.1” address, port 80, specified through `PG_PROBACKUP_S3_PORT`, will be used.

If any of the specified addresses gets unavailable while `pg_probackup` is in operation, requests to the S3 storage are distributed between the rest of the specified addresses. That is, when several addresses are specified, `pg_probackup` performs load balancing of S3 requests.

`PG_PROBACKUP_S3_PORT`

The port of the S3 server.

`PG_PROBACKUP_S3_REGION`

The region of the S3 server.

`PG_PROBACKUP_S3_BUCKET_NAME`

The name of the bucket on the S3 server.

PG\_PROBACKUP\_S3\_ACCESS\_KEY  
PG\_PROBACKUP\_S3\_SECRET\_ACCESS\_KEY

Secure tokens on the S3 server.

PG\_PROBACKUP\_S3\_HTTPS

The protocol to be used. Possible values:

- ON or HTTPS — use HTTPS
- Other than ON or HTTPS — use HTTP

PG\_PROBACKUP\_S3\_BUFFER\_SIZE

The size of the read/write buffer for communicating with S3, in MiB. The default is 16.

PG\_PROBACKUP\_S3\_RETRIES

The maximum number of attempts to execute an S3 request in case of failures. The default is 3.

PG\_PROBACKUP\_S3\_TIMEOUT

The maximum amount of time to execute an HTTP request to the S3 server, in seconds. The default is 300.

PG\_PROBACKUP\_S3\_IGNORE\_CERT\_VER

Don't verify the certificate host and peer. The default is ON.

PG\_PROBACKUP\_S3\_CA\_CERTIFICATE

Specify the path to file with trust Certificate Authority (CA) bundle.

PG\_PROBACKUP\_S3\_CA\_PATH

Specify the directory with trust CA certificates.

PG\_PROBACKUP\_S3\_CLIENT\_CERT

Setup SSL client certificate.

PG\_PROBACKUP\_S3\_CLIENT\_KEY

Setup private key file for TLS and SSL client certificate.

### S3 Required Permissions

The following minimal permissions to the target S3 bucket should be granted for the access key used by pg\_probackup with versioning disabled:

- for the [init](#) command:

```
s3:GetBucketVersioning
s3:ListBucket
```

- for the [add-instance](#), [set-config](#), and [set-backup](#) commands:

```
s3:GetBucketVersioning
s3:ListBucket
s3:PutObject
```

- for the [del-instance](#) command:

```
s3:GetBucketVersioning
s3:ListBucket
s3>DeleteObject
```

- for the [backup](#) and [merge](#) commands:

```
s3:ListBucket
s3:PutObject
s3:GetBucketVersioning
s3:AbortMultipartUpload
s3:GetObject
s3>DeleteObject
```

- for the [archive-push](#) command:

```
s3:ListBucket
s3:PutObject
s3:GetBucketVersioning
s3:AbortMultipartUpload
s3:GetObject
```

- for the [restore](#), [show](#), and [show-config](#) commands:

```
s3:GetBucketVersioning
s3:GetObject
s3:ListBucket
```

- for the [validate](#) command:

```
s3:GetBucketVersioning
s3:GetObject
s3:ListBucket
s3:PutObject
s3>DeleteObject
```

- for the [delete](#) and [maintain](#) commands:

```
s3:GetBucketVersioning
s3:GetObject
s3:ListBucket
s3>DeleteObject
```

When versioning is enabled, the following additional permissions are required:

- `s3:ListBucketVersions` for all commands that require `s3:ListBucket`
- `s3>DeleteObjectVersion` for all commands that require `s3>DeleteObject`

## Setting up PTRACK Backups

### Note

PTRACK versions lower than 2.0 are deprecated and not supported. Postgres Pro Standard and Postgres Pro Enterprise versions starting with 11.9.1 contain PTRACK 2.0. Upgrade your server to avoid issues in backups that you will take in future and be sure to take fresh backups of your clusters with the upgraded PTRACK since the backups taken with PTRACK 1.x might be corrupt.

If you are going to use PTRACK backups, complete the following additional steps.

### Note

The permissions required for the role that will perform PTRACK backups (the `backup` role in the examples below) are listed in [the section called “Configuring the Database Cluster”](#). The role must have permissions only in the database used for connection to the Postgres Pro server.

For Postgres Pro 11 or higher:

1. Create PTRACK extension in the database *used for connection* to the Postgres Pro server:

```
CREATE EXTENSION ptrack;
```

2. To enable tracking page updates, set `ptrack.map_size` parameter to a positive integer and restart the server.

For optimal performance, it is recommended to set `ptrack.map_size` to  $N / 1024$ , where  $N$  is the size of the Postgres Pro cluster, in MB. If you set this parameter to a lower value, PTRACK is more likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the incremental backup. Setting `ptrack.map_size` to a higher value does not affect PTRACK operation, but it is not recommended to set this parameter to a value higher than 1024.

### Note

If you change the `ptrack.map_size` parameter value, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. Thus, you have to retake a full backup before taking incremental PTRACK backups after changing `ptrack.map_size`.

## Usage

### Creating a Backup

To create a backup, run the following command:

```
pg_probackup backup -B backup_dir --instance=instance_name -b backup_mode
```

Where `backup_mode` can take one of the following values: [FULL](#), [DELTA](#), [PAGE](#), and [PTRACK](#).

When restoring a cluster from an incremental backup, `pg_probackup` relies on the parent full backup and all the incremental backups between them, which is called “the backup chain”. Thus, to perform incremental backups, it is necessary to have the last parent full backup with the status `OK` or `DONE` in the directory. If the parent full backup has the `MERGING` or `MERGED` status, an incremental backup cannot be performed.

For example, if merge has already been launched with a single full backup, an attempt to perform an incremental backup will end with the following messages:

```
WARNING: Valid full backup on current timeline 1 is not found, trying to look up on
previous timelines
WARNING: Cannot find valid backup on previous timelines
ERROR: Create new full backup before an incremental one
```

### ARCHIVE Mode

ARCHIVE is the default WAL delivery mode.

For example, to make a FULL backup in ARCHIVE mode, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL
```

ARCHIVE backups rely on [continuous archiving](#) to get WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

When a backup is taken, `pg_probackup` ensures that WAL files containing WAL records between `Start LSN` and `Stop LSN` actually exist in `backup_dir/wal/instance_name` directory. `pg_probackup` also ensures that WAL records between `Start LSN` and `Stop LSN` can be parsed. This precaution eliminates the risk of silent WAL corruption.

### STREAM Mode

STREAM is the optional WAL delivery mode.

For example, to make a FULL backup in the STREAM mode, add the `--stream` flag to the command from the previous example:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --stream --temp-slot
```

The optional `--temp-slot` flag ensures that the required segments remain available if the WAL is rotated before the backup is complete.

Unlike backups in ARCHIVE mode, STREAM backups include all the WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

During [backup](#) `pg_probackup` streams WAL files containing WAL records between `Start LSN` and `Stop LSN` to `backup_dir/backups/instance_name/backup_id/database/pg_wal` directory. To eliminate the risk of silent WAL corruption, `pg_probackup` also checks that WAL records between `Start LSN` and `Stop LSN` can be parsed.

Even if you are using [continuous archiving](#), STREAM backups can still be useful in the following cases:

- STREAM backups can be restored on the server that has no file access to WAL archive.
- STREAM backups enable you to restore the cluster state at the point in time for which WAL files in archive are no longer available.
- Backup in STREAM mode can be taken from a standby of a server that generates small amount of WAL traffic, without long waiting for WAL segment to fill up.

#### Page Validation

If [data\\_checksums](#) are enabled in the database cluster, `pg_probackup` uses this information to check correctness of data files during backup. While reading each page, `pg_probackup` checks whether the calculated checksum coincides with the checksum stored in the page header. This guarantees that the Postgres Pro instance and the backup itself have no corrupt pages. Note that `pg_probackup` reads database files directly from the filesystem, so under heavy write load during backup it can show false-positive checksum mismatches because of partial writes. If a page checksum mismatch occurs, the page is re-read and checksum comparison is repeated.

A page is considered corrupt if checksum comparison has failed more than 300 times. In this case, the backup is aborted.

Even if data checksums are not enabled, `pg_probackup` always performs sanity checks for page headers.

#### External Directories

To back up a directory located outside of the data directory, use the optional `--external-dirs` parameter that specifies the path to this directory. If you would like to add more than one external directory, you can provide several paths separated by colons on Linux systems or semicolons on Windows systems.

For example, to include `/etc/dir1` and `/etc/dir2` directories into the full backup of your `instance_name` instance that will be stored under the `backup_dir` directory on Linux, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --external-dirs=/etc/dir1:/etc/dir2
```

Similarly, to include `C:\dir1` and `C:\dir2` directories into the full backup on Windows, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --external-dirs=C:\dir1;C:\dir2
```

`pg_probackup` recursively copies the contents of each external directory into a separate subdirectory in the backup catalog. Since external directories included into different backups do not have to be the same, when you are restoring the cluster from an incremental backup, only those directories that belong to this particular backup will be restored. Any external directories stored in the previous backups will be ignored.

To include the same directories into each backup of your instance, you can specify them in the `pg_probackup.conf` configuration file using the [set-config](#) command with the `--external-dirs` option.

## Performing Cluster Verification

To verify that Postgres Pro database cluster is not corrupt, run the following command:

```
pg_probackup checkdb [-B backup_dir [--instance=instance_name]] [-D data_dir]
[connection_options]
```

This command performs physical verification of all data files located in the specified data directory by running page header sanity checks, as well as block-level checksum verification if checksums are enabled. If a corrupt page is detected, `checkdb` continues cluster verification until all pages in the cluster are validated.

By default, similar [page validation](#) is performed automatically while a backup is taken by `pg_probackup`. The `checkdb` command enables you to perform such page validation on demand, without taking any backup copies, even if the cluster is not backed up using `pg_probackup` at all.

To perform cluster verification, `pg_probackup` needs to connect to the cluster to be verified. In general, it is enough to specify the backup instance of this cluster for `pg_probackup` to determine the required connection options. However, if `-B` and `--instance` options are omitted, you have to provide [connection options](#) and `data_dir` via environment variables or command-line options.

Physical verification cannot detect logical inconsistencies, missing or nullified blocks and entire files, or similar anomalies. Extensions [amcheck](#) and [amcheck\\_next](#) provide a partial solution to these problems.

If you would like, in addition to physical verification, to verify all indexes in all databases using these extensions, you can specify the `--amcheck` flag when running the `checkdb` command:

```
pg_probackup checkdb -D data_dir --amcheck [connection_options]
```

You can skip physical verification by specifying the `--skip-block-validation` flag. In this case, you can omit `backup_dir` and `data_dir` options, only [connection options](#) are mandatory:

```
pg_probackup checkdb --amcheck --skip-block-validation [connection_options]
```

Logical verification can be done more thoroughly with the `--heapallindexed` flag by checking that all heap tuples that should be indexed are actually indexed, but at the higher cost of CPU, memory, and I/O consumption.

## Validating a Backup

`pg_probackup` calculates checksums for each file in a backup during the backup process. The process of checking checksums of backup data files is called *the backup validation*. By default, validation is run immediately after the backup is taken and right before the restore, to detect possible backup corruption.

### Note

The backup validation includes checking checksums for CFS files.

If you would like to skip backup validation, you can specify the `--no-validate` flag when running [backup](#) and [restore](#) commands.

To ensure that all the required backup files are present and can be used to restore the database cluster, you can run the [validate](#) command with the exact [recovery target options](#) you are going to use for recovery.

For example, to check that you can restore the database cluster from a backup copy up to transaction ID 4242, run this command:

```
pg_probackup validate -B backup_dir --instance=instance_name --recovery-target-xid=4242
```

If validation completes successfully, `pg_probackup` displays the corresponding message. If validation fails, you will receive an error message with the exact time, transaction ID, and LSN up to which the recovery is possible.

If you specify *backup\_id* via `-i/--backup-id` option, then only the backup copy with specified backup ID will be validated. If *backup\_id* is specified with [recovery target options](#), the `validate` command will check whether it is possible to restore the specified backup to the specified recovery target.

For example, to check that you can restore the database cluster from a backup copy with the `SBOL6P` backup ID up to the specified timestamp, run this command:

```
pg_probackup validate -B backup_dir --instance=instance_name -i SBOL6P --recovery-  
target-time="2024-04-10 18:18:26+03"
```

If you specify the *backup\_id* of an incremental backup, all its parents starting from FULL backup will be validated.

If you omit all the parameters, all backups are validated.

## Restoring a Cluster

To restore the database cluster from a backup, run the [restore](#) command with at least the following options:

```
pg_probackup restore -B backup_dir --instance=instance_name -i backup_id
```

Where:

- *backup\_dir* is the backup catalog that stores all backup files and meta information.
- *instance\_name* is the backup instance for the cluster to be restored.
- *backup\_id* specifies the backup to restore the cluster from. If you omit this option, `pg_probackup` uses the latest valid backup available for the specified instance. If you specify an incremental backup to restore, `pg_probackup` automatically restores the underlying full backup and then sequentially applies all the necessary increments.

Once the `restore` command is complete, start the database service.

If you restore [ARCHIVE](#) backups, perform [PITR](#), or specify the `--restore-as-replica` flag with the `restore` command to set up a standby server, `pg_probackup` creates a recovery configuration file once all data files are copied into the target directory. This file includes the minimal settings required for recovery, except for the password in the [primary\\_conninfo](#) parameter; you have to add the password manually or use the `--primary-conninfo` option, if required. For Postgres Pro 11, recovery settings are written into the `recovery.conf` file. Starting from Postgres Pro 12, `pg_probackup` writes these settings into the `probackup_recovery.conf` file and then includes it into `postgresql.auto.conf`.

If you are restoring a `STREAM` backup, the restore is complete at once, with the cluster returned to a self-consistent state at the point when the backup was taken. For `ARCHIVE` backups, Postgres Pro replays all available archived WAL segments, so the cluster is restored to the latest state possible within the current timeline. You can change this behavior by using the [recovery target options](#) with the `restore` command, as explained in [the section called “Performing Point-in-Time \(PITR\) Recovery”](#).

If the cluster to restore contains tablespaces, `pg_probackup` restores them to their original location by default. To restore tablespaces to a different location, use the `--tablespace-mapping/-T` option. Otherwise, restoring the cluster on the same host will fail if tablespaces are in use, because the backup would have to be written to the same directories.

When using the `--tablespace-mapping/-T` option, you must provide absolute paths to the old and new tablespace directories. If a path happens to contain an equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces. For example:

```
pg_probackup restore -B backup_dir --instance=instance_name -D data_dir -j 4 -  
i backup_id -T tablespace1_dir=tablespace1_newdir -T tablespace2_dir=tablespace2_newdir
```

To restore the cluster on a remote host, follow the instructions in [the section called “Using pg\\_probackup in the Remote Mode”](#).

## Note

By default, the `restore` command validates the specified backup before restoring the cluster. If you run regular backup validations and would like to save time when restoring the cluster, you can specify the `--no-validate` flag to skip validation and speed up the recovery.

### Incremental Restore

The speed of restore from backup can be significantly improved by replacing only invalid and changed pages in already existing Postgres Pro data directory using [incremental restore options](#) with the `restore` command.

To restore the database cluster from a backup in incremental mode, run the `restore` command with the following options:

```
pg_probackup restore -B backup_dir --instance=instance_name -D data_dir -
I incremental_mode
```

Where `incremental_mode` can take one of the following values:

- **CHECKSUM** — read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with checksum and LSN not matching with corresponding page in backup. This is the simplest, the most fool-proof incremental mode. Recommended to use by default.
- **LSN** — read the `pg_control` in the data directory to obtain redo LSN and redo TLI, which allows you to determine a point in history(shiftpoint), where data directory state shifted from target backup chain history. If shiftpoint is not within reach of backup chain history, then restore is aborted. If shiftpoint is within reach of backup chain history, then read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with LSN greater than shiftpoint. This mode offers a greater speed up compared to CHECKSUM, but rely on two conditions to be met. First, [data checksums](#) parameter must be enabled in data directory (to avoid corruption due to hint bits). This condition will be checked at the start of incremental restore and the operation will be aborted if checksums are disabled. Second, the `pg_control` file must be synched with state of data directory. This condition cannot be checked at the start of restore, so it is a user responsibility to ensure that `pg_control` contain valid information. Therefore it is not recommended to use LSN mode in any situation, where `pg_control` cannot be trusted or has been tampered with: after `pg_resetxlog` execution, after restore from backup without recovery been run, etc.
- **NONE** — regular restore without any incremental optimizations.

Regardless of chosen incremental mode, `pg_probackup` will check, that postmaster in given destination directory is not running and `system-identifier` is the same as in the backup.

Suppose you want to return an old primary as a replica after switchover using incremental restore in LSN mode:

| Instance<br>Data | Version<br>WAL | ID<br>Zalg | Recovery Time<br>Zratio       | Recovery Time |            | Mode  | WAL Mode | TLI | Time |
|------------------|----------------|------------|-------------------------------|---------------|------------|-------|----------|-----|------|
|                  |                |            |                               | Start LSN     | Stop LSN   |       |          |     |      |
| node             | 17             | SBOL8S     | 2024-04-09 18:19:43.707720+03 | DELTA         | STREAM     | 16/15 |          |     |      |
| 3s 114MB         | 64MB           | lz4        | 1.42                          | 0/3C003020    | 0/3E8D4930 | OK    |          |     |      |
| node             | 17             | SBOL8G     | 2024-04-09 18:19:32.594670+03 | PTRACK        | STREAM     | 15/15 |          |     |      |

```

### Note

Incremental restore is possible only for backups with `program_version` equal or greater than 2.4.0.

#### Partial Restore

If you have enabled [partial restore](#) before taking backups, you can restore only some of the databases using [partial restore options](#) with the [restore](#) commands.

To restore the specified databases only, run the [restore](#) command with the following options:

```
pg_probackup restore -B backup_dir --instance=instance_name --db-include=database_name
```

The `--db-include` option can be specified multiple times. For example, to restore only databases `db1` and `db2`, run the following command:

```
pg_probackup restore -B backup_dir --instance=instance_name --db-include=db1 --db-include=db2
```

To exclude one or more databases from restore, use the `--db-exclude` option:

```
pg_probackup restore -B backup_dir --instance=instance_name --db-exclude=database_name
```

The `--db-exclude` option can be specified multiple times. For example, to exclude the databases `db1` and `db2` from restore, run the following command:

```
pg_probackup restore -B backup_dir --instance=instance_name --db-exclude=db1 --db-exclude=db2
```

Partial restore relies on lax behavior of Postgres Pro recovery process toward truncated files. For recovery to work properly, files of excluded databases are restored as files of zero size. After the Postgres Pro cluster is successfully started, you must drop the excluded databases using `DROP DATABASE` command.

To decouple a single cluster containing multiple databases into separate clusters with minimal downtime, you can do partial restore of the cluster as a standby using the `--restore-as-replica` option for specific databases.

**Note**

The `template0` and `template1` databases are always restored.

**Note**

Due to recovery specifics of Postgres Pro versions earlier than 12, it is advisable that you set the `hot standby` parameter to `off` when running partial restore of a Postgres Pro cluster of version earlier than 12. Otherwise the recovery may fail.

**Performing Point-in-Time (PITR) Recovery**

If you have enabled [continuous WAL archiving](#) before taking backups, you can restore the cluster to its state at an arbitrary point in time (recovery target) using [recovery target options](#) with the `restore` command.

You can use both STREAM and ARCHIVE backups for point in time recovery as long as the WAL archive is available at least starting from the time the backup was taken. If `-i/--backup-id` option is omitted, `pg_probackup` automatically chooses the backup that is the closest to the specified recovery target and starts the restore process, otherwise `pg_probackup` will try to restore the specified backup to the specified recovery target.

- To restore the cluster state at the exact time, specify the `--recovery-target-time` option, in the timestamp format. For example:

```
pg_probackup restore -B backup_dir --instance=instance_name --recovery-target-time="2024-04-10 18:18:26+03"
```

- To restore the cluster state up to a specific transaction ID, use the `--recovery-target-xid` option:

```
pg_probackup restore -B backup_dir --instance=instance_name --recovery-target-xid=687
```

- To restore the cluster state up to the specific LSN, use `--recovery-target-lsn` option:

```
pg_probackup restore -B backup_dir --instance=instance_name --recovery-target-lsn=16/B374D848
```

- To restore the cluster state up to the specific named restore point, use `--recovery-target-name` option:

```
pg_probackup restore -B backup_dir --instance=instance_name --recovery-target-name="before_app_upgrade"
```

- To restore the backup to the latest state available in the WAL archive, use `--recovery-target` option with `latest` value:

```
pg_probackup restore -B backup_dir --instance=instance_name --recovery-target="latest"
```

- To restore the cluster to the earliest point of consistency, use `--recovery-target` option with the `immediate` value:

```
pg_probackup restore -B backup_dir --instance=instance_name --recovery-target='immediate'
```

**Using pg\_probackup in the Remote Mode**

`pg_probackup` supports the remote mode that allows you to perform `backup` and `restore` operations remotely via SSH. In this mode, the backup catalog is stored on a local system, while Postgres Pro instance to be backed up is located on a remote system. You must have `pg_probackup` installed on both systems.

**Note**

`pg_probackup` relies on passwordless SSH connection for communication between the hosts.

**Note**

In addition to SSH connection, `pg_probackup` uses a regular connection to the database to manage the remote operation. See the section [Configuring the Database Cluster](#) for details of how to set up a database connection.

The typical workflow is as follows:

- On your backup host, configure `pg_probackup` as explained in the section [Installation and Setup](#). For the [add-instance](#) and [set-config](#) commands, make sure to specify [remote mode options](#) that point to the database host with the Postgres Pro instance.
- If you would like to take remote backups in [PAGE](#) mode, or rely on [ARCHIVE](#) WAL delivery mode, or use [PITR](#), configure continuous WAL archiving from the database host to the backup host as explained in the section [Setting up continuous WAL archiving](#). For the [archive-push](#) and [archive-get](#) commands, you must specify the [remote mode options](#) that point to the backup host with the backup catalog.
- Run [backup](#) or [restore](#) commands with [remote mode options on the backup host](#). `pg_probackup` connects to the remote system via SSH and creates a backup locally or restores the previously taken backup on the remote system, respectively.

For example, to create an archive full backup of a Postgres Pro cluster located on a remote system with host address `192.168.0.2` on behalf of the `postgres` user via SSH connection through port `2302`, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --remote-user=postgres --remote-host=192.168.0.2 --remote-port=2302
```

To restore the latest available backup on a remote system with host address `192.168.0.2` on behalf of the `postgres` user via SSH connection through port `2302`, run:

```
pg_probackup restore -B backup_dir --instance=instance_name --remote-user=postgres --remote-host=192.168.0.2 --remote-port=2302
```

Restoring an [ARCHIVE](#) backup or performing [PITR](#) in the remote mode require additional information: destination address, port and username for establishing an SSH connection **from** the host with database **to** the host with the backup catalog. This information will be used by the `restore_command` to copy WAL segments from the archive to the Postgres Pro `pg_wal` directory.

To solve this problem, you can use [Remote WAL Archive Options](#).

For example, to restore latest backup on remote system using remote mode through SSH connection to user `postgres` on host with address `192.168.0.2` via port `2302` and user `backup` on backup catalog host with address `192.168.0.3` via port `2303`, run:

```
pg_probackup restore -B backup_dir --instance=instance_name --remote-user=postgres --remote-host=192.168.0.2 --remote-port=2302 --archive-host=192.168.0.3 --archive-port=2303 --archive-user=backup
```

Provided arguments will be used to construct the `restore_command`:

```
restore_command = '"install_dir/pg_probackup" archive-get -B "backup_dir" --instance=instance_name --wal-file-path=%p --wal-file-name=%f --remote-host=192.168.0.3 --remote-port=2303 --remote-user=backup'
```

Alternatively, you can use the `--restore-command` option to provide the entire `restore_command`:

```
pg_probackup restore -B backup_dir --instance=instance_name --remote-user=postgres --remote-host=192.168.0.2 --remote-port=2302 --restore-command='"install_dir/
```

```
pg_probackup" archive-get -B "backup_dir" --instance=instance_name --wal-file-path=%p
--wal-file-name=%f --remote-host=192.168.0.3 --remote-port=2303 --remote-user=backup'
```

### Note

The remote mode is currently unavailable for Windows systems.

## Running pg\_probackup on Parallel Threads

[backup](#), [restore](#), [merge](#), [delete](#), [catchup](#), [checkdb](#), and [validate](#) processes can be executed on several parallel threads. This can significantly speed up pg\_probackup operation given enough resources (CPU cores, disk, and network bandwidth).

Parallel execution is controlled by the `-j/--threads` command-line option. For example, to create a backup using four parallel threads, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL -j 4
```

### Note

Parallel restore applies only to copying data from the backup catalog to the data directory of the cluster. When Postgres Pro server is started, WAL records need to be replayed, and this cannot be done in parallel.

### Important

A technique is implemented that prevents repeatable copying of one file when pg\_probackup runs on multiple threads. With this technique, however, when disks are slow or the system is overloaded, parallel copying might fail. To handle this situation, resolve issues with your system resources.

## Configuring pg\_probackup

Once the backup catalog is initialized and a new backup instance is added, you can use the `pg_probackup-up.conf` configuration file located in the `backup_dir/backups/instance_name` directory to fine-tune pg\_probackup configuration.

For example, [backup](#) and [checkdb](#) commands use a regular Postgres Pro connection. To avoid specifying [connection options](#) each time on the command line, you can set them in the `pg_probackup.conf` configuration file using the [set-config](#) command.

### Note

It is **not recommended** to edit `pg_probackup.conf` manually.

Initially, `pg_probackup.conf` contains the following settings:

- `PGDATA` — the path to the data directory of the cluster to back up.
- `system-identifier` — the unique identifier of the Postgres Pro instance.

Additionally, you can define [remote mode](#), [retention](#), [logging](#), and [compression](#) settings using the `set-config` command:

```
pg_probackup set-config -B backup_dir --instance=instance_name
[--external-dirs=external_directory_path] [remote_options] [connection_options]
[retention_options] [logging_options]
```

To view the current settings, run the following command:

```
pg_probackup show-config -B backup_dir --instance=instance_name
```

You can override the settings defined in `pg_probackup.conf` when running `pg_probackup` [commands](#) via the corresponding environment variables and/or command line options.

### Specifying Connection Settings

If you define connection settings in the `pg_probackup.conf` configuration file, you can omit connection options in all the subsequent `pg_probackup` commands. However, if the corresponding environment variables are set, they get higher priority. The options provided on the command line overwrite both environment variables and configuration file settings.

If nothing is given, the default values are taken. By default `pg_probackup` tries to use local connection via Unix domain socket (`localhost` on Windows) and tries to get the database name and the user name from the `PGUSER` environment variable or the current OS user name.

### Managing the Backup Catalog

With `pg_probackup`, you can manage backups from the command line:

- [View backup information](#)
- [View WAL Archive Information](#)
- [Validate backups](#)
- [Merge backups](#)
- [Delete backups](#)

### Viewing Backup Information

To view the list of existing backups for every instance, run the command:

```
pg_probackup show -B backup_dir
```

`pg_probackup` displays the list of all the available backups. For example:

```
BACKUP INSTANCE 'node'
```

| Instance | Version |     | ID   | Recovery Time |            |                    | Mode   | WAL Mode | TLI | Time |

For each backup, the following information is provided:

- Instance — the instance name.
- Version — Postgres Pro major version.
- ID — the backup identifier.
- Recovery time — the earliest moment for which you can restore the state of the database cluster.
- Mode — the method used to take this backup. Possible values: FULL, PAGE, DELTA, PTRACK.
- WAL Mode — WAL delivery mode. Possible values: STREAM and ARCHIVE.
- TLI — timeline identifiers of the current backup and its parent.
- Time — the time it took to perform the backup.

- **Data** — the size of the data files in this backup. This value does not include the size of WAL files. For STREAM backups, the total size of the backup can be calculated as `Data + WAL`.
- **WAL** — the uncompressed size of WAL files that need to be applied during recovery for the backup to reach a consistent state.
- **compress-alg** — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `lz4`, `zstd`, `none`.
- **Zratio** — compression ratio calculated as “uncompressed-bytes” / “data-bytes”.
- **Start LSN** — WAL log sequence number corresponding to the start of the backup process. REDO point for Postgres Pro recovery process to start from.
- **Stop LSN** — WAL log sequence number corresponding to the end of the backup process. Consistency point for Postgres Pro recovery process.
- **Status** — backup status. Possible values:
  - **OK** — the backup is complete and valid.
  - **DONE** — the backup is complete, but was not validated.
  - **RUNNING** — the backup is in progress.
  - **MERGING** — the backup is being merged.
  - **MERGED** — the backup data files were successfully merged, but its metadata is in the process of being updated. Only full backups can have this status.
  - **DELETING** — the backup files are being deleted.
  - **CORRUPT** — some of the backup files are corrupt.
  - **ERROR** — the backup was aborted because of an unexpected error.
  - **ORPHAN** — the backup is invalid because one of its parent backups is corrupt or missing.
  - **HIDDEN\_FOR\_TEST** — a test script marked the backup as nonexistent. (`pg_probackup` never sets this status by itself.)

You can restore the cluster from the backup only if the backup status is `OK` or `DONE`.

To get more detailed information about the backup, run the `show` command with the backup ID:

```
pg_probackup show -B backup_dir --instance=instance_name -i backup_id
```

The sample output is as follows:

```
#Configuration
backup-mode = FULL
stream = false
compress-alg = lz4
compress-level = 1
from-replica = false

#Compatibility
block-size = 8192
xlog-block-size = 8192
checksum-version = 1
program-version = 2.7.3
server-version = 17

#Result backup info
timelineid = 1
start-lsn = 0/41000028
stop-lsn = 0/420000C0
start-time = '2024-04-09 18:19:52+03'
end-time = '2024-04-09 18:19:58+03'
end-validation-time = '2024-04-09 18:19:59+03'
recovery-xid = 757
recovery-time = '2024-04-09 18:19:56.603355+03'
```

```
data-bytes = 395651278
wal-bytes = 16777216
uncompressed-bytes = 578552566
pgdata-bytes = 578552248
status = OK
primary_conninfo = 'user=backup channel_binding=prefer host=localhost
port=5432 sslmode=prefer sslcompression=0 sslcertmode=allow sslsni=1
ssl_min_protocol_version=TLSv1.2 gssencmode=prefer krbsrvname=postgres gssdelegation=0
target_session_attrs=any load_balance_hosts=disable'
content-crc = 3862224379
```

Detailed output has additional attributes:

- `compress-alg` — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `lz4`, `zstd`, `none`.
- `compress-level` — compression level used during backup.
- `from-replica` — was this backup taken on a standby? Possible values: `1`, `0`.
- `block-size` — the [block\\_size](#) setting of Postgres Pro cluster at the backup start.
- `checksum-version` — are [data\\_checksums](#) enabled in the backed up Postgres Pro cluster? Possible values: `1`, `0`.
- `program-version` — full version of `pg_probackup` binary used to create the backup.
- `start-time` — the backup start time.
- `end-time` — the backup end time.
- `end-validation-time` — the backup validation end time.
- `expire-time` — the point in time when a pinned backup can be removed in accordance with retention policy. This attribute is only available for pinned backups.
- `uncompressed-bytes` — the size of data files before adding page headers and applying compression. You can evaluate the effectiveness of compression by comparing `uncompressed-bytes` to `data-bytes` if compression is used.
- `pgdata-bytes` — the size of Postgres Pro cluster data files at the time of backup. You can evaluate the effectiveness of an incremental backup by comparing `pgdata-bytes` to `uncompressed-bytes`.
- `recovery-xid` — transaction ID at the backup end time.
- `parent-backup-id` — ID of the parent backup. Available only for incremental backups.
- `primary_conninfo` — libpq connection parameters used to connect to the Postgres Pro cluster to take this backup. The password is not included.
- `note` — text note attached to backup.
- `content-crc` — CRC32 checksum of `backup_content.control` file. It is used to detect corruption of backup meta-information.

You can also get the detailed information about the backup in the JSON format:

```
pg_probackup show -B backup_dir --instance=instance_name --format=json -i backup_id
```

The sample output is as follows:

```
[
  {
    "instance": "node",

]
```

Viewing WAL Archive Information

To view the information about WAL archive for every instance, run the command:

```
pg_probackup show -B backup_dir [--instance=instance_name] --archive
```

pg\_probackup displays the list of all the available WAL files grouped by timelines. For example:

```
ARCHIVE INSTANCE 'node'
```

| TLI      | Parent TLI | Switchpoint | Min Segno                  | Max Segno                  | N  |
|----------|------------|-------------|----------------------------|----------------------------|----|
| segments | Size       | Zratio      | N backups                  | Status                     |    |
| 1        | 0          | 0/0         | 0000000100000000000000001B | 00000001000000000000000042 | 40 |
|          | 640MB      | 1.00        | 5                          | OK                         |    |

For each timeline, the following information is provided:

- TLI — timeline identifier.
- Parent TLI — identifier of the timeline from which this timeline branched off.
- Switchpoint — LSN of the moment when the timeline branched off from its parent timeline.
- Min Segno — the first WAL segment belonging to the timeline.
- Max Segno — the last WAL segment belonging to the timeline.
- N segments — number of WAL segments belonging to the timeline.
- Size — the size that files take on disk.
- Zalg — compression algorithm used during backup. Possible values: zlib, pglz, lz4, zstd, none.
- Zratio — compression ratio calculated as  $N \text{ segments} * wal\_segment\_size * wal\_block\_size / \text{Size}$ .
- N backups — number of backups belonging to the timeline. To get the details about backups, use the JSON format.
- Status — status of the WAL archive for this timeline. Possible values:
  - OK — all WAL segments between Min Segno and Max Segno are present.
  - DEGRADED — some WAL segments between Min Segno and Max Segno are missing. To find out which files are lost, view this report in the JSON format. This status may appear if several WAL files (in the middle of the sequence) were deleted by the `delete` command with the `--delete-wal`

option according to the retention policy. This status does not affect the restore correctness, but it can be impossible to perform PITR of the cluster to some recovery targets.

To get more detailed information about the WAL archive in the JSON format, run the command:

```
pg_probackup show -B backup_dir [--instance=instance_name] --archive --format=json
```

The sample output is as follows:

```
[
  {
    "instance": "node",

Most fields are consistent with the plain format, with some exceptions:

- The size is in bytes.
- The `closest-backup-id` attribute contains the ID of the most recent valid backup that belongs to one of the previous timelines. You can use this backup to perform point-in-time recovery to this timeline. If such a backup does not exist, this string is empty.
- The `lost-segments` array provides with information about intervals of missing segments in `DEGRADED` timelines. In `OK` timelines, the `lost-segments` array is empty.
- The `backups` array lists all backups belonging to the timeline. If the timeline has no backups, this array is empty.

## Configuring Retention Policy

With `pg_probackup`, you can configure retention policy to remove redundant backups, clean up unneeded WAL files, as well as pin specific backups to ensure they are kept for the specified time, as explained in the sections below. All these actions can be combined together in any way.

### Removing Redundant Backups

By default, all backup copies created with `pg_probackup` are stored in the specified backup catalog. To save disk space, you can configure retention policy to remove redundant backup copies.

To configure retention policy, set one or more of the following variables in the `pg_probackup.conf` file via [set-config](#):

```
--retention-redundancy=redundancy
```

Specifies **the number of full backup copies** to keep in the backup catalog.

```
--retention-window=window
```

Defines the earliest point in time for which `pg_probackup` can complete the recovery. This option is set in **the number of days** from the current moment. For example, if `retention-window=7`, `pg_probackup` must keep at least one backup copy that is older than seven days, with all the corresponding WAL files, and all the backups that follow.

If both `--retention-redundancy` and `--retention-window` options are set, both these conditions have to be taken into account when purging the backup catalog. For example, if you set `--retention-redundancy=2` and `--retention-window=7`, `pg_probackup` has to keep two full backup copies, as well as all the backups required to ensure recoverability for the last seven days:

```
pg_probackup set-config -B backup_dir --instance=instance_name --retention-redundancy=2
--retention-window=7
```

It is recommended to always keep at least two last parent full backups to avoid errors when creating incremental backups.

To clean up the backup catalog in accordance with retention policy, you have to run the `delete` command with `retention flags`, as shown below, or use the `backup` command with these flags to process the outdated backup copies right when the new backup is created.

For example, to remove all backup copies that no longer satisfy the defined retention policy, run the following command with the `--delete-expired` flag:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired
```

If you would like to also remove the WAL files that are no longer required for any of the backups, you should also specify the `--delete-wal` flag:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired --delete-wal
```

You can also set or override the current retention policy by specifying `--retention-redundancy` and `--retention-window` options directly when running `delete` or `backup` commands:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired --retention-window=7 --retention-redundancy=2
```

Since incremental backups require that their parent full backup and all the preceding incremental backups are available, if any of such backups expire, they still cannot be removed while at least one incremental backup in this chain satisfies the retention policy. To avoid keeping expired backups that are still required to restore an active incremental one, you can merge them with this backup using the `--merge-expired` flag when running `backup` or `delete` commands.

Suppose you have backed up the `node` instance in the `backup_dir` directory, with the `--retention-window` option set to 6 and `--retention-redundancy` option set to 2, and you have the following backups available on August 01, 2024:

```
BACKUP INSTANCE 'node'
```

| Instance                   | Version | ID     | Recovery Time |            |             | Mode   | WAL Mode | TLI | Time | Data   |

| node                       | 17      |        | SGT4B1        | 2024-07-18 | 09:49:52+03 | FULL   | ARCHIVE  | 1/0 | 5s   | 11MB   |
| 16MB                       | zstd    | 2,89   | 0/2000028     | 0/3003A28  | OK          |        |          |     |      |        |

If you run the `delete` command with the `--delete-expired` flag, the backups with IDs `SGT4B1`, `SGUYZ2`, and `SGWTN3` will be removed as they are expired both according to the retention window and due to redundancy (the required set of full backups has already been retained). `SGUYZ2` and `SGWTN3` will also be removed since the base full backup is expired.

Running the `delete` command with the `--merge-expired` flag will merge backups `SH48B3` and `SH62Z5` with `SH9SB5`. The merge will occur with `SH9SB5` as it is the first non-expired delta backup, which can be merged with expired delta backups `SH62Z5` and expired full backup `SH48B3`.

```
pg_probackup delete -B backup_dir --instance=node --delete-expired --merge-expired
pg_probackup show -B backup_dir
```

```
BACKUP INSTANCE 'node'
```

The `Time` field for the merged backup displays the time required for the merge.

### Pinning Backups

If you need to keep certain backups longer than the established retention policy allows, you can pin them for arbitrary time. For example:

```
pg_probackup set-backup -B backup_dir --instance=instance_name -i backup_id --ttl=30d
```

This command sets the expiration time of the specified backup to 30 days starting from the time indicated in its `recovery-time` attribute.

You can also explicitly set the expiration time for a backup using the `--expire-time` option. For example:

```
pg_probackup set-backup -B backup_dir --instance=instance_name -i backup_id --expire-time="2027-04-09 18:21:32+00"
```

Alternatively, you can use the `--ttl` and `--expire-time` options with the `backup` command to pin the newly created backup:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --ttl=30d
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --expire-time="2027-04-09 18:21:32+00"
```

To check if the backup is pinned, run the `show` command:

```
pg_probackup show -B backup_dir --instance=instance_name -i backup_id
```

If the backup is pinned, it has the `expire-time` attribute that displays its expiration time:

```
...
recovery-time = '2024-04-09 18:21:32+00'
expire-time = '2027-04-09 18:21:32+00'
data-bytes = 22288792
...
```

You can unpin the backup by setting the `--ttl` option to zero:

```
pg_probackup set-backup -B backup_dir --instance=instance_name -i backup_id --ttl=0
```

### Note

A pinned incremental backup implicitly pins all its parent backups. If you unpin such a backup later, its implicitly pinned parents will also be automatically unpinned.

### Configuring WAL Archive Retention Policy

When [continuous WAL archiving](#) is enabled, archived WAL segments can take a lot of disk space. Even if you delete old backup copies from time to time, the `--delete-wal` flag can purge only those WAL segments that do not apply to any of the remaining backups in the backup catalog. However, if point-in-time recovery is critical only for the most recent backups, you can configure WAL archive retention policy to keep WAL archive of limited depth and win back some more disk space.

To configure WAL archive retention policy, you have to run the `set-config` command with the `--wal-depth` option that specifies the number of backups that can be used for PITR. This setting applies to all the timelines, so you should be able to perform PITR for the same number of backups on each timeline, if available. [Pinned backups](#) are not included into this count: if one of the latest backups is pinned, `pg_probackup` ensures that PITR is possible for one extra backup.

To remove WAL segments that do not satisfy the defined WAL archive retention policy, you simply have to run the `delete` or `backup` command with the `--delete-wal` flag. For archive backups, WAL segments between `Start LSN` and `Stop LSN` are always kept intact, so such backups remain valid regardless of the `--wal-depth` setting and can still be restored, if required.

You can also use the `--wal-depth` option with the `delete` and `backup` commands to override the previously defined WAL archive retention policy and purge old WAL segments on the fly.

Suppose you have backed up the `node` instance in the `backup_dir` directory and configured [continuous WAL archiving](#):

```
pg_probackup show -B backup_dir --instance=node
```

| Instance | Version | ID   | Recovery Time |                               | Mode       | WAL Mode | TLI | Time |

You can check the state of the WAL archive by running the `show` command with the `--archive` flag:

```
pg_probackup show -B backup_dir --instance=node --archive
```

```
ARCHIVE INSTANCE 'node'
```

| TLI segments | Parent | TLI Size | Switchpoint Zratio | Min Segno N backups       | Segno Status | Max Segno                 | N  |
|--------------|--------|----------|--------------------|---------------------------|--------------|---------------------------|----|
| 1            | 0      | 480MB    | 0/0 1.00 6         | 0000000100000000000000052 | OK           | 000000010000000000000006F | 30 |

WAL purge without `--wal-depth` cannot achieve much, only one segment is removed:

```
pg_probackup delete -B backup_dir --instance=node --delete-wal
```

```
ARCHIVE INSTANCE 'node'
```

| TLI segments | Parent | TLI Size | Switchpoint Zratio | Min Segno N backups       | Segno Status | Max Segno                 | N  |
|--------------|--------|----------|--------------------|---------------------------|--------------|---------------------------|----|
| 1            | 0      | 448MB    | 0/0 1.00 6         | 0000000100000000000000054 | OK           | 000000010000000000000006F | 28 |

If you would like, for example, to keep only those WAL segments that can be applied to the latest valid backup, set the `--wal-depth` option to 1:

```
pg_probackup delete -B backup_dir --instance=node --delete-wal --wal-depth=1
```

```
ARCHIVE INSTANCE 'node'
```

| TLI segments | Parent | TLI Size | Switchpoint Zratio | Min Segno N backups       | Segno Status | Max Segno                 | N |
|--------------|--------|----------|--------------------|---------------------------|--------------|---------------------------|---|
| 1            | 0      | 16MB     | 0/0 1.00 6         | 000000010000000000000006F | OK           | 000000010000000000000006F | 1 |

Alternatively, you can use the `--wal-depth` option with the [backup](#) command:

```
pg_probackup backup -B backup_dir --instance=node -b DELTA --wal-depth=1 --delete-wal
```

```
ARCHIVE INSTANCE 'node'
```

| TLI segments | Parent | TLI Size | Switchpoint Zratio | Min Segno N backups       | Segno Status | Max Segno                 | N |
|--------------|--------|----------|--------------------|---------------------------|--------------|---------------------------|---|
| 1            | 0      | 16MB     | 0/0 1.00 7         | 0000000100000000000000071 | OK           | 0000000100000000000000071 | 1 |

## Merging Backups

As you take more and more incremental backups, the total size of the backup catalog can substantially grow. To save disk space, you can merge incremental backups to their parent full backup by running the `merge` command, specifying the backup ID of the most recent incremental backup you would like to merge:

```
pg_probackup merge -B backup_dir --instance=instance_name -i backup_id
```

This command merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup, it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant. Thus, the merge operation is virtually equivalent to retaking a full backup and removing all the outdated backups, but it allows you to save much time, especially for large data volumes, as well as I/O and network traffic if you are using `pg_probackup` in the [remote](#) mode.

Before the merge, `pg_probackup` validates all the affected backups to ensure that they are valid. You can check the current backup status by running the [show](#) command with the backup ID:

```
pg_probackup show -B backup_dir --instance=instance_name -i backup_id
```

If the merge is still in progress, the backup status is displayed as `MERGING`. For full backups, it can also be shown as `MERGED` while the metadata is being updated at the final stage of the merge. The merge is idempotent, so you can restart the merge if it was interrupted.

### Warning

Avoid force-terminating the merge operation, as it may cause subsequent `merge` commands to fail and disrupt backup validation.

## Deleting Backups

To delete a backup that is no longer required, run the following command:

```
pg_probackup delete -B backup_dir --instance=instance_name -i backup_id
```

This command will delete the backup with the specified `backup_id`, together with all the incremental backups that descend from `backup_id`, if any. This way you can delete some recent incremental backups, retaining the underlying full backup and some of the incremental backups that follow it.

To delete obsolete WAL files that are not necessary to restore any of the remaining backups, use the `--delete-wal` flag:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-wal
```

To delete backups that are expired according to the current retention policy, use the `--delete-expired` flag:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired
```

Expired backups cannot be removed while at least one incremental backup that satisfies the retention policy is based on them. If you would like to minimize the number of backups still required to keep incremental backups valid, specify the `--merge-expired` flag when running this command:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired --merge-expired
```

In this case, `pg_probackup` searches for the oldest incremental backup that satisfies the retention policy and merges this backup with the underlying full and incremental backups that have already expired, thus making it a full backup. Once the merge is complete, the remaining expired backups are deleted.

Before merging or deleting backups, you can run the `delete` command with the `--dry-run` flag, which displays the status of all the available backups according to the current retention policy, without performing any irreversible actions.

To delete all backups with specific status, use the `--status`:

```
pg_probackup delete -B backup_dir --instance=instance_name --status=ERROR
```

Deleting backups by status ignores established retention policies.

## Cloning and Synchronizing Postgres Pro Instance

`pg_probackup` can create a copy of a Postgres Pro instance directly, without using the backup catalog. To do this, you can run the `catchup` command. It can be useful in the following cases:

- To add a new standby server.

Usually, `pg_basebackup` is used to create a copy of a Postgres Pro instance. If the data directory of the destination instance is empty, the `catchup` command works similarly, but it can be faster if run in parallel mode.

- To have a fallen-behind standby server “catch up” with the primary.

Under write-intensive load, replicas may fail to replay WAL fast enough to keep up with the primary and hence may lag behind. A usual solution to create a new replica and switch to it requires a lot of extra space and data transfer. The `catchup` command allows you to update an existing replica much faster by bringing differences from the primary.

`catchup` is different from other `pg_probackup` operations:

- The backup catalog is not required.
- STREAM WAL delivery mode is only supported.
- Copying external directories is not supported.
- DDL commands `CREATE TABLESPACE/DROP TABLESPACE` cannot be run simultaneously with `catchup`.
- `catchup` takes configuration files, such as `postgresql.conf`, `postgresql.auto.conf`, or `pg_hba.conf`, from the source server and overwrites them on the target server. The `--exclude-path` option allows you to keep the configuration files intact.

To prepare for cloning/synchronizing a Postgres Pro instance, set up the source server as follows:

- [Configure the database cluster](#) for the instance to copy.
- To copy from a remote server, [configure the remote mode](#).
- To use the PTRACK `catchup` mode, [set up PTRACK backups](#).

Before cloning/synchronizing a Postgres Pro instance, ensure that the source server is running and accepting connections. To clone/sync a Postgres Pro instance, on the server with the destination instance, you can run the `catchup` command as follows:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --  
destination-pgdata=path_to_local_dir --stream [connection_options] [remote_options]
```

Where *catchup\_mode* can take one of the following values:

- `FULL` — creates a full copy of the Postgres Pro instance. The data directory of the destination instance must be empty for this mode.
- `DELTA` — reads all data files in the data directory and creates an incremental copy for pages that have changed since the destination instance was shut down.
- `PTRACK` — tracking page changes on the fly, only reads and copies pages that have changed since the point of divergence of the source and destination instances.

### Warning

PTRACK `catchup` mode requires PTRACK not earlier than 2.0 and hence, Postgres Pro not earlier than 11.

By specifying the `--stream` option, you can set `STREAM` WAL delivery mode of copying, which will include all the necessary WAL files by streaming them from the server via replication protocol.

You can use [connection\\_options](#) to specify the connection to the source database cluster. If it is located on a different server, also specify [remote\\_options](#).

If the source database cluster contains tablespaces that must be located in a different directory, additionally specify the `--tablespace-mapping` option:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --  
destination-pgdata=path_to_local_dir --stream --tablespace-mapping=OLDDIR=NEWDIR
```

To run the `catchup` command on parallel threads, specify the number of threads with the `--threads` option:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --  
destination-pgdata=path_to_local_dir --stream --threads=num_threads
```

Before cloning/synchronising a Postgres Pro instance, you can run the `catchup` command with the `--dry-run` flag to estimate the size of data files to be transferred, but make no changes on disk:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --  
destination-pgdata=path_to_local_dir --stream --dry-run
```

For example, assume that a remote standby server with the Postgres Pro instance having `/replica-pgdata` data directory has fallen behind. To sync this instance with the one in `/master-pgdata` data directory, you can run the `catchup` command in the `PTRACK` mode on four parallel threads as follows:

```
pg_probackup catchup --source-pgdata=/master-pgdata --destination-pgdata=/replica-  
pgdata -p 5432 -d postgres -U remote-postgres-user --stream --backup-mode=PTRACK  
--remote-host=remote-hostname --remote-user=remote-unix-username -j 4 --exclude-  
path=postgresql.conf --exclude-path=postgresql.auto.conf --exclude-path=pg_hba.conf --  
exclude-path=pg_ident.conf
```

Note that in this example, the configuration files will not be overwritten during synchronization.

Another example shows how you can add a new remote standby server with the Postgres Pro data directory `/replica-pgdata` by running the `catchup` command in the `FULL` mode on four parallel threads:

```
pg_probackup catchup --source-pgdata=/master-pgdata --destination-pgdata=/replica-  
pgdata -p 5432 -d postgres -U remote-postgres-user --stream --backup-mode=FULL --  
remote-host=remote-hostname --remote-user=remote-unix-username -j 4
```

## Command-Line Reference

### Commands

This section describes `pg_probackup` commands. Optional parameters are enclosed in square brackets. For detailed parameter descriptions, see the section [Options](#).

#### version

```
pg_probackup version [--format=json]
```

Prints `pg_probackup` version and edition, as well as Postgres Pro version and edition.

If `--format=json` is specified, the output is printed in the JSON format. This may be needed for native integration with JSON-based applications, such as PPEM. Example of a JSON output:

```
pg_probackup version --format=json  
{  
  "pg_probackup":  
  {  
    "version": "2.8.2",  
    "edition": "enterprise"  
  },  
  "database":  
  {  
    "type": "Postgres Pro Enterprise",  
    "version": "16.3.1"  
  },  
  "compressions": [zlib, pglz, lz4, zstd]  
}
```

#### help

```
pg_probackup help [command]
```

Displays the synopsis of `pg_probackup` commands. If one of the `pg_probackup` commands is specified, shows detailed information about the options that can be used with this command.

**init**

```
pg_probackup init -B backup_dir [--skip-if-exists] [s3_options] [--help]
[logging_options]
```

Initializes the backup catalog in *backup\_dir* that will store backup copies, WAL archive, and meta information for the backed up database clusters. If the specified *backup\_dir* already exists, it must be empty. Otherwise, `pg_probackup` displays a corresponding error message. You can ignore this error by specifying the `--skip-if-exists` option. Although the backup will not be initialized, the application will return 0 code.

For details, see the section [Initializing the Backup Catalog](#).

**add-instance**

```
pg_probackup add-instance -B backup_dir -D data_dir --instance=instance_name
[--skip-if-exists] [s3_options] [--help] [--wal-tree] [logging_options]
```

Initializes a new backup instance inside the backup catalog *backup\_dir* and generates the `pg_probackup.conf` configuration file that controls `pg_probackup` settings for the cluster with the specified *data\_dir* data directory.

`--skip-if-exists`

Allows skipping initialization without raising an error if an instance already exists.

`--wal-tree`

Sets WAL files to be stored in subdirectories, optimizing disk space. This prevents file system overload, especially NFS (Network File System), which can struggle with excessive files in a single directory.

For more details on the `add-instance` command, see the section [Adding a New Backup Instance](#).

**del-instance**

```
pg_probackup del-instance -B backup_dir --instance=instance_name [s3_options] [--help]
[logging_options]
```

Deletes all backups and WAL files associated with the specified instance.

**set-config**

```
pg_probackup set-config -B backup_dir --instance=instance_name
[--help] [--pgdata=pgdata-path]
[--retention-redundancy=redundancy] [--retention-window=window] [--wal-depth=wal_depth]
[--compress-algorithm=compression_algorithm] [--compress-level=compression_level]
[-d dbname] [-h host] [-p port] [-U username]
[--archive-timeout=timeout] [--external-dirs=external_directory_path]
[--restore-command=cmdline]
[remote_options] [remote_wal_archive_options] [logging_options] [s3_options]
```

Adds the specified connection, compression, retention, logging, and external directory settings into the `pg_probackup.conf` configuration file, or modifies the previously defined values.

For all available settings, see the [Options](#) section.

It is **not recommended** to edit `pg_probackup.conf` manually.

**set-backup**

```
pg_probackup set-backup -B backup_dir --instance=instance_name -i backup_id
```

```
{--ttl=ttl | --expire-time=time}  
[--note=backup_note] [s3_options] [--help] [logging_options]
```

Sets the provided backup-specific settings into the `backup.control` configuration file, or modifies the previously defined values.

```
--note=backup_note
```

Sets the text note for backup copy. If `backup_note` contains newline characters, then only the substring before the first newline character will be saved. The maximum size of a text note is 1 KB. The `'none'` value removes the current note.

For all available pinning settings, see the section [Pinning Options](#).

### show-config

```
pg_probackup show-config -B backup_dir --instance instance_name [--format=plain|json]  
[s3_options]  
[--no-scale-units] [logging_options]
```

Displays all the current `pg_probackup` configuration settings, including those that are specified in the `pg_probackup.conf` configuration file located in the `backup_dir/backups/instance_name` directory and those that were provided on a command line. You can specify the `--format=json` option to get the result in the JSON format. By default, configuration settings are shown as plain text.

You can also specify the `--no-scale-units` option to display time and memory configuration settings in their base (unscaled) units. Otherwise, the values are scaled to larger units for optimal display. For example, if `archive-timeout` is 300, then 5min is displayed, but if `archive-timeout` is 301, then 301s is displayed. Also, if the `--no-scale-units` option is specified, configuration settings are displayed without units and for the JSON format, numeric and boolean values are not enclosed in quotes. This facilitates parsing the output.

To edit `pg_probackup.conf`, use the [set-config](#) command.

### show

```
pg_probackup show -B backup_dir  
[--help] [--instance=instance_name [-i backup_id | --archive]] [--format=plain|json]  
[--no-color] [--show-symlinks] [s3_options]  
[logging_options]
```

Shows the contents of the backup catalog. If `instance_name` and `backup_id` are specified, shows detailed information about this backup. If the `--archive` option is specified, shows the contents of WAL archive of the backup catalog.

By default, the contents of the backup catalog is shown as plain text. You can specify the `--format=json` option to get the result in the JSON format. If `--no-color` flag is used, then the output is not colored.

If the `--show-symlinks` option is specified, the command also shows the links between [merged](#) backups and the original full backups that incremental backups were merged to.

For details on usage, see the sections [Managing the Backup Catalog](#) and [Viewing WAL Archive Information](#).

### backup

```
pg_probackup backup -B backup_dir -b backup_mode --instance=instance_name  
[--help] [-j num_threads] [--progress]  
[--backup-threads num_threads] [--validate-threads num_threads]  
[-C] [--stream [-S slot_name] [--temp-slot=[true|false|on|off]]] [--backup-pg-log]  
[--no-validate] [--skip-block-validation]  
[-w --no-password] [-W --password] [--allow-group-access]
```

```
[--write-rate-limit=bitrate]  
[--archive-timeout=timeout] [--external-dirs=external_directory_path]  
[--no-sync] [--note=backup_note]  
[connection_options] [compression_options] [remote_options]  
[retention_options] [pinning_options] [logging_options] [s3_options]
```

Creates a backup copy of the Postgres Pro instance.

`-b mode`

`--backup-mode=mode`

Specifies the backup mode to use. Possible values are: [FULL](#), [DELTA](#), [PAGE](#), and [PTRACK](#).

`--backup-threads num_threads`

Specifies the number of threads for copying files. Overrides the `j/--threads` option for file copying.

`--validate-threads num_threads`

Specifies the number of threads for the backup validation. Overrides the `j/--threads` option for the backup validation.

`-C`

`--smooth-checkpoint`

Spreads out the checkpoint over a period of time. By default, `pg_probackup` tries to complete the checkpoint as soon as possible.

`--stream`

Makes a [STREAM](#) backup, which includes all the necessary WAL files by streaming them from the database server via replication protocol.

`--temp-slot [=true|false|on|off]`

Creates a *temporary* physical replication slot for streaming WAL from the backed up Postgres Pro instance. `--temp-slot` is enabled by default. It ensures that all the required WAL segments remain available if WAL is rotated while the backup is in progress. This flag can only be used together with the `--stream` flag. The default slot name is `pg_probackup_slot`. To change it, use the `--slot/-S` option and explicitly specify `--temp-slot` or `--temp-slot=true|on`.

`-S slot_name`

`--slot=slot_name`

Specifies the replication slot to connect to for WAL streaming. This option can only be used together with the `--stream` flag.

`--backup-pg-log`

Includes the log directory into the backup. This directory usually contains log messages. By default, log directory is excluded.

`-E external_directory_path`

`--external-dirs=external_directory_path`

Includes the specified directory into the backup by recursively copying its contents into a separate subdirectory in the backup catalog. This option is useful to back up scripts, SQL dump files, and configuration files located outside of the data directory. If you would like to back up several external directories, separate their paths by a colon on Unix and a semicolon on Windows.

`--allow-group-access`

Provides read access to backups stored on the backup host to any OS user in the same group as the OS user on the backup host who runs `pg_probackup` operations.

`--write-rate-limit=bitrate`

Sets the rate of writing data to disk, in MBps or GBps. The default unit is MBps. For example: `--write-rate-limit=1GBps` or `--write-rate-limit=100` (MBps). The default value is 0 — no limitation.

If this option is specified, the following information is displayed at the end of the backup:

- `written` — the amount of data written, in MB.
- `total time` — the time that elapsed between the first and last writes, in seconds. Note that this is not the total backup time.
- `sleep time` — the amount of forced delay time, in seconds.
- `average rate` — the actual average write rate, in MBps.

For example:

```
INFO: Rate limit: written 14975.445 MB, total time 17.163 s, sleep time 2.370 s,
      average rate 872.560715 MBps
```

`--archive-timeout=wait_time`

Sets the timeout for WAL segment archiving and streaming, in seconds. By default, `pg_probackup` waits 300 seconds.

`--skip-block-validation`

Disables block-level checksum verification to speed up the backup process.

`--no-validate`

Skips automatic validation after the backup is taken. You can use this flag if you validate backups regularly and would like to save time when running backup operations.

It is recommended to use this flag when creating a backup to an S3 storage. Due to some features of S3 storages, automatic validation may appear incorrect in this case. Skip automatic validation and then perform validation using a separate [validate](#) command.

`--no-sync`

Do not sync backed up files to disk. You can use this flag to speed up the backup process. Using this flag can result in data corruption in case of operating system or hardware crash. If you use this option, it is recommended to run the [validate](#) command once the backup is complete to detect possible issues.

`--note=backup_note`

Sets the text note for backup copy. If `backup_note` contain newline characters, then only substring before first newline character will be saved. Max size of text note is 1 KB. The `'none'` value removes current note.

For more details of the command settings, see sections [Common Options](#), [Connection Options](#), [Retention Options](#), [Pinning Options](#), [Remote Mode Options](#), [Compression Options](#), [Logging Options](#), and [S3 Options](#).

For details on usage, see the section [Creating a Backup](#).

## restore

```
pg_probackup restore -B backup_dir --instance=instance_name
[--help] [--dry-run] [-D data_dir] [-i backup_id]
[-j num_threads] [--progress]
```

```
[-T OLDDIR=NEWDIR] [--external-mapping=OLDDIR=NEWDIR] [--skip-external-dirs]
[-R | --restore-as-replica] [--no-validate] [--skip-block-validation]
[--force] [--no-sync] [--allow-group-access]
[--restore-command=cmdline]
[--primary-conninfo=primary_conninfo]
[-S | --primary-slot-name=slot_name]
[-X wal_dir | --waldir=wal_dir]
[recovery_target_options] [logging_options] [remote_options]
[partial_restore_options] [remote_wal_archive_options] [s3_options]
```

Restores the Postgres Pro instance from a backup copy located in the *backup\_dir* backup catalog. If you specify a [recovery target option](#), `pg_probackup` finds the closest backup and restores it to the specified recovery target. If neither the backup ID nor recovery target options are provided, `pg_probackup` uses the most recent backup to perform the recovery.

`-R`  
`--restore-as-replica`

Creates a minimal recovery configuration file to facilitate setting up a standby server. If the replication connection requires a password, you must specify the password manually in the [primary\\_conninfo](#) parameter as it is not included. For Postgres Pro 11 or lower, recovery settings are written into the `recovery.conf` file. Starting from Postgres Pro 12, `pg_probackup` writes these settings into the `probackup_recovery.conf` file in the data directory, and then includes them into the `postgresql.auto.conf` when the cluster is started.

`--primary-conninfo=primary_conninfo`

Sets the [primary\\_conninfo](#) parameter to the specified value. This option will be ignored unless the `-R` flag is specified.

**Example:** `--primary-conninfo="host=192.168.1.50 port=5432 user=foo password=foopass"`

`-S`  
`--primary-slot-name=slot_name`

Sets the [primary\\_slot\\_name](#) parameter to the specified value. This option will be ignored unless the `-R` flag is specified.

`-T OLDDIR=NEWDIR`  
`--tablespace-mapping=OLDDIR=NEWDIR`

Relocates the tablespace from the *OLDDIR* to the *NEWDIR* directory at the time of recovery. Both *OLDDIR* and *NEWDIR* must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces.

`--external-mapping=OLDDIR=NEWDIR`

Relocates an external directory included into the backup from the *OLDDIR* to the *NEWDIR* directory at the time of recovery. Both *OLDDIR* and *NEWDIR* must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple directories.

`--skip-external-dirs`

Skip external directories included into the backup with the `--external-dirs` option. The contents of these directories will not be restored.

`--skip-block-validation`

Disables block-level checksum verification to speed up validation. During automatic validation before the restore only file-level checksums will be verified.

`--no-validate`

Skips backup validation. You can use this flag if you validate backups regularly and would like to save time when running restore operations.

`--allow-group-access`

Provides any OS user in the same group as the cluster owner with the same access to the `PGDATA` directory on the database server as the cluster owner has. Running `restore` with this option will set the same permissions as when the cluster is created using the command

```
initdb --group access
```

`--restore-command=cmdline`

Sets the `restore_command` parameter to the specified command. For example: `--restore-command='cp /mnt/server/archivedir/%f "%p"'`

`--force`

Allows to ignore an invalid status of the backup. You can use this flag if you need to restore the Postgres Pro cluster from a corrupt or an invalid backup. Use with caution. If `PGDATA` contains a non-empty directory with system ID different from that of the backup being restored, [incremental restore](#) with this flag overwrites the directory contents (while an error occurs without the flag). If tablespaces are remapped through the `--tablespace-mapping` option into non-empty directories, the contents of such directories will be deleted.

`--no-sync`

Do not sync restored files to disk. You can use this flag to speed up restore process. Using this flag can result in data corruption in case of operating system or hardware crash. If it happens, you have to run the `restore` command again.

`-X wal_dir`

`--waldir=wal_dir`

Sets the directory to write WAL files to. By default WAL files will be placed in the `pg_wal` subdirectory of the target directory, but this option can be used to place them elsewhere. `wal_dir` must be an absolute path, which must not already exist, but if it does, it must be empty.

For more details of the command settings, see sections [Common Options](#), [Recovery Target Options](#), [Remote Mode Options](#), [Remote WAL Archive Options](#), [Logging Options](#), [Partial Restore Options](#), and [S3 Options](#).

For details on usage, see the section [Restoring a Cluster](#).

## checkdb

`pg_probackup checkdb`

`[-B backup_dir] [--instance=instance_name] [-D data_dir]`

`[--help] [-j num_threads] [--progress]`

`[--amcheck] [--skip-block-validation] [--checkunique] [--heapallindexed]]`

`[connection_options] [logging_options]`

`[s3_options]`

Verifies the Postgres Pro database cluster correctness by detecting physical and logical corruption.

For the command to work correctly, when the backup instance is created in the S3 storage, you must specify [S3 options](#) on the command line or through environment variables.

`--amcheck`

Performs logical verification of indexes for the specified Postgres Pro instance if no corruption was found while checking data files. You must have the [amcheck](#) extension or the `amcheck_next` extension

installed in the database to check its indexes. For databases without amcheck, index verification will be skipped. Additional options `--checkunique` and `--heapallindexed` are effective depending on the version of amcheck installed.

`--checkunique`

Verifies unique constraints during logical verification of indexes. You can use this flag only together with the `--amcheck` flag when the amcheck extension is installed in the database.

The verification of unique constraints is only possible if in the version of the amcheck extension you are using, the `bt_index_check` function takes the `checkunique` parameter.

`--heapallindexed`

Checks that all heap tuples that should be indexed are actually indexed. You can use this flag only together with the `--amcheck` flag.

This check is only possible if in the version of the amcheck/amcheck\_next extension you are using, the `bt_index_check` function takes the `heapallindexed` parameter.

`--skip-block-validation`

Skip validation of data files. You can use this flag only together with the `--amcheck` flag, so that only logical verification of indexes is performed.

For more details of the command settings, see sections [Common Options](#), [Connection Options](#), [Logging Options](#), and [S3 Options](#).

For details on usage, see the section [Verifying a Cluster](#).

## validate

```
pg_probackup validate -B backup_dir
[--help] [--instance=instance_name] [-i backup_id]
[-j num_threads] [--progress] [--wal]
[--skip-block-validation]
[recovery_target_options] [logging_options] [s3_options]
```

Verifies that all the files required to restore the cluster are present and are not corrupt. If *instance\_name* is not specified, `pg_probackup` validates all backups available in the backup catalog. If you specify the *instance\_name* without any additional options, `pg_probackup` validates all the backups available for this backup instance. If you specify the *instance\_name* with a [recovery target option](#) and/or a *backup\_id*, `pg_probackup` checks whether it is possible to restore the cluster using these options. If the `--wal` option is specified, full check of the WAL archive will be performed instead of only checking WAL segments needed to restore the cluster.

For details, see the section [Validating a Backup](#).

## Note

The `TATLIN.OBJECT` S3 storage is an “eventually consistent” class system. In such systems, the reconciliation across nodes proceeds asynchronously. Therefore, if you are making a backup to the `TATLIN.OBJECT` S3 storage, perform backup validation not immediately after the backup, but some time later.

## merge

```
pg_probackup merge -B backup_dir --instance=instance_name -i backup_id
[--dry-run] [--help] [-j num_threads] [--progress] [--no-validate] [--no-sync]
[logging_options]
```

Merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup, it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant.

`--no-validate`

Skips automatic validation before and after merge.

`--no-sync`

Do not sync merged files to disk. You can use this flag to speed up the merge process. Using this flag can result in data corruption in case of operating system or hardware crash.

For more details of the command settings, see sections [Common Options](#) and [Merging Backups](#).

#### **delete**

```
pg_probackup delete -B backup_dir --instance=instance_name
[--help] [-j num_threads] [--progress]
[--retention-redundancy=redundancy] [--retention-window=window] [--wal-depth=wal_depth]
[--delete-wal]
{-i backup_id | --delete-expired [--merge-expired] | --merge-expired | --
status=backup_status}
[--dry-run] [--no-validate] [--no-sync] [logging_options] [s3_options]
```

Deletes backup with specified *backup\_id* or launches the retention purge of backups and archived WAL that do not satisfy the current retention policies.

`--no-validate`

Skips automatic validation before and after retention merge.

`--no-sync`

Do not sync merged files to disk. You can use this flag to speed up the retention merge process. Using this flag can result in data corruption in case of operating system or hardware crash.

For details, see the sections [Deleting Backups](#), [Retention Options](#), and [Configuring Retention Policy](#).

#### **archive-push**

```
pg_probackup archive-push -B backup_dir --instance=instance_name
--wal-file-name=wal_file_name [--wal-file-path=wal_file_path]
[--help] [--dry-run] [--no-sync] [--compress] [--no-ready-rename] [--overwrite]
[-j num_threads] [--batch-size=batch_size]
[--archive-timeout=timeout]
[--compress-algorithm=compression_algorithm]
[--compress-level=compression_level]
[remote_options] [logging_options] [s3_options]
```

Copies WAL files into the corresponding subdirectory of the backup catalog and validates the backup instance by *instance\_name* and *system-identifier*. If parameters of the backup instance and the cluster do not match, this command fails with the following error message: `Refuse to push WAL segment segment_name into archive. Instance parameters mismatch.`

If the files to be copied already exists in the backup catalog, `pg_probackup` computes and compares their checksums. If the checksums match, `archive-push` skips the corresponding file and returns a successful execution code. Otherwise, `archive-push` fails with an error. If you would like to replace WAL files in the case of checksum mismatch, run the `archive-push` command with the `--overwrite` flag.

Each file is copied to a temporary file with the `.part` suffix. If the temporary file already exists, `pg_probackup` will wait `archive_timeout` seconds before discarding it. After the copy is done, atomic rename is performed. This algorithm ensures that a failed `archive-push` will not stall continuous archiv-

ing and that concurrent archiving from multiple sources into a single WAL archive has no risk of archive corruption.

The Postgres Pro server requests WAL segments one at a time. To speed up archiving, you can specify the `--batch-size` option to copy WAL segments in batches of the specified size. If `--batch-size` option is used, then you can also specify the `-j` option to copy the batch of WAL segments on multiple threads.

WAL segments copied to the archive are synced to disk unless the `--no-sync` flag is used.

You can use `archive-push` in the [archive\\_command](#) Postgres Pro parameter to set up [continuous WAL archiving](#).

For more details of the command settings, see sections [Common Options](#), [Archiving Options](#), [Compression Options](#), and [S3 Options](#).

#### **archive-get**

```
pg_probackup archive-get -B backup_dir --instance=instance_name --wal-file-  
path=wal_file_path --wal-file-name=wal_file_name  
[-j num_threads] [--batch-size=batch_size]  
[--prefetch-dir=prefetch_dir_path] [--no-validate-wal]  
[--dry-run] [--help] [remote_options] [logging_options] [s3_options]
```

Copies WAL files from the corresponding subdirectory of the backup catalog to the cluster's write-ahead log location. This command is automatically set by `pg_probackup` as part of the `restore_command` when restoring backups using a WAL archive. You do not need to set it manually if you use local storage for backups or remote mode.

If you use S3 interface, to ensure that the Postgres Pro server has access to S3 storage to fetch WAL files during restore, you can specify the `--s3-config-file` option that defines the S3 configuration file with appropriate configuration settings, as described in [the section called “S3 Options”](#).

The Postgres Pro server requests WAL segments one at a time. To speed up recovery, you can specify the `--batch-size` option to copy WAL segments in batches of the specified size. If `--batch-size` option is used, then you can also specify the `-j` option to copy the batch of WAL segments on multiple threads.

For more details of the command settings, see sections [Common Options](#), [Archiving Options](#), [Compression Options](#), and [S3 Options](#).

#### **catchup**

```
pg_probackup catchup -b catchup_mode  
--source-pgdata=path_to_pgdata_on_remote_server  
--destination-pgdata=path_to_local_dir  
[--help] [-j | --threads=num_threads] [--dry-run]  
[--write-rate-limit=bitrate]  
[--stream [--temp-slot[=true|false|on|off]] [-P | --perm-slot] [-S | --slot=slot_name]]  
[--exclude-path=PATHNAME]  
[-T OLDDIR=NEWDIR]  
[-X | --waldir=wal_dir]  
[connection_options] [remote_options]  
[logging_options]
```

Creates a copy of a Postgres Pro instance without using the backup catalog.

```
-b catchup_mode  
--backup-mode=catchup_mode
```

Specifies the catchup mode to use. Possible values are: [FULL](#), [DELTA](#), and [PTRACK](#).

```
--source-pgdata=path_to_pgdata_on_remote_server
```

Specifies the path to the data directory of the instance to be copied. The path can be local or remote.

`--destination-pgdata=path_to_local_dir`

Specifies the path to the local data directory to copy to.

`-j num_threads`

`--threads=num_threads`

Sets the number of parallel threads for `catchup` process.

`--stream`

Copies the instance in **STREAM** WAL delivery mode, including all the necessary WAL files by streaming them from the server via replication protocol. For `catchup`, it is enabled by default.

`--write-rate-limit=bitrate`

Sets the rate of writing data to disk, in MBps or GBps. The default unit is MBps. For example: `--write-rate-limit=1GBps` or `--write-rate-limit=100` (MBps). The default value is 0 — no limitation.

If this option is specified, the following information is displayed at the end of the `catchup` operation:

- `written` — the amount of data written, in MB.
- `total time` — the time that elapsed between the first and last writes, in seconds. Note that this is not the total duration of the `catchup` operation.
- `sleep time` — the amount of forced delay time, in seconds.
- `average rate` — the actual average write rate, in MBps.

For example:

```
INFO: Rate limit: written 14975.445 MB, total time 17.163 s, sleep time 2.370 s,
      average rate 872.560715 MBps
```

`-x=path_prefix`

`--exclude-path=path_prefix`

Specifies a prefix for files to exclude from the synchronization of Postgres Pro instances during copying. The prefix must contain a path relative to the data directory of an instance. If the prefix specifies a directory, all files in this directory will not be synchronized.

### Warning

This option is dangerous since excluding files from synchronization can result in incomplete synchronization; use with care.

`--temp-slot[=true|false|on|off]`

Creates a *temporary* physical replication slot for streaming WAL from the Postgres Pro instance being copied. `--temp-slot` is enabled by default. It ensures that all the required WAL segments remain available if WAL is rotated while the backup is in progress. This flag can only be used together with the `--stream` flag and cannot be used together with the `--perm-slot` flag. The default slot name is `pg_probackup_slot`. To change it, use the `--slot/-S` option and explicitly specify `--temp-slot` or `--temp-slot=true|on`.

`-P`

`--perm-slot`

Creates a *permanent* physical replication slot for streaming WAL from the Postgres Pro instance being copied. This flag can only be used together with the `--stream` flag and cannot be used together with the `--temp-slot` flag. The default slot name is `pg_probackup_perm_slot`, which can be changed using the `--slot/-S` option.

```
-S slot_name
--slot=slot_name
```

Specifies the replication slot to connect to for WAL streaming. This option can only be used together with the `--stream` flag.

```
-T OLDDIR=NEWDIR
--tablespace-mapping=OLDDIR=NEWDIR
```

Relocates the tablespace from the `OLDDIR` to the `NEWDIR` directory at the time of recovery. Both `OLDDIR` and `NEWDIR` must be absolute paths. If the path contains the equals sign (`=`), escape it with a backslash. This option can be specified multiple times for multiple tablespaces.

```
-X wal_dir
--waldir=wal_dir
```

Sets the directory to write WAL files to. By default WAL files will be placed in the `pg_wal` subdirectory of the target directory, but this option can be used to place them elsewhere. `wal_dir` must be an absolute path, which must not already exist, but if it does, it must be empty to perform `catchup` with `--catchup-mode=FULL`.

For more details of the command settings, see sections [Common Options](#), [Connection Options](#), and [Remote Mode Options](#).

For details on usage, see the section [Cloning and Synchronizing Postgres Pro Instance](#).

## **maintain**

```
pg_probackup maintain --B backup_dir --instance=instance_name
[-i backup_id] --status-sync [--help] [--dry-run]
[--log-level-console=log-level-console] [--log-level-file=log-level-file]
[--log-format-console=log-format-console] [--log-format-file=log-format-file]
[--log-filename=log-filename]
```

Performs a cleanup of the directory with backups of the specified instance after a forced termination of previous `pg_probackup` commands.

```
--status-sync
```

Detects expired locks and hanging backups, as well as updates backup statuses.

For more details of the command settings, see sections [Common Options](#) and [Logging Options](#).

## **Options**

This section describes command-line options for `pg_probackup` commands. If the option value can be derived from an environment variable, this variable is specified below the command-line option, in the uppercase. Some values can be taken from the `pg_probackup.conf` configuration file located in the backup catalog.

For details, see [the section called “Configuring pg\\_probackup”](#).

If an option is specified using more than one method, command-line input has the highest priority, while the `pg_probackup.conf` settings have the lowest priority.

## **Common Options**

The list of general options.

```
--dry-run
```

Initiates a trial run of the appropriate command, which does not actually do any changes, that is, it does not create, delete or move files on disk. This flag allows you to check that all the command options are correct and the command is ready to run. WAL streaming is skipped with `--dry-run`.

```
-B directory
--backup-path=directory
BACKUP_PATH
```

Specifies the absolute path to the backup catalog. Backup catalog is a directory where all backup files and meta information are stored. Since this option is required for most of the `pg_probackup` commands, you are recommended to specify it once in the `BACKUP_PATH` environment variable. In this case, you do not need to use this option each time on the command line.

```
-D directory
--pgdata=directory
PGDATA
```

Specifies the absolute path to the data directory of the database cluster. This option is mandatory only for the `add-instance` command. Other commands can take its value from the `PGDATA` environment variable, or from the `pg_probackup.conf` configuration file.

```
-i backup_id
--backup-id=backup_id
```

Specifies the unique identifier of the backup.

```
--instance instance_name
```

Specifies the name of the Postgres Pro instance.

```
-j num_threads
--threads=num_threads
```

Sets the number of parallel threads for backup, restore, merge, validate, checkdb, and archive-push processes.

```
--progress
```

Shows the progress of operations.

```
--help
```

Shows detailed information about the options that can be used with this command.

### Recovery Target Options

If `continuous WAL archiving` is configured, you can use one of these options together with `restore` or `validate` commands to specify the moment up to which the database cluster must be restored or validated.

```
--recovery-target=immediate|latest
```

Defines when to stop the recovery:

- The `immediate` value stops the recovery after reaching the consistent state of the specified backup, or the latest available backup if the `-i/--backup-id` option is omitted. This is the default behavior for STREAM backups.
- The `latest` value continues the recovery until all WAL segments available in the archive are applied. Setting this value of `--recovery-target` also sets `--recovery-target-timeline` to `latest`.

```
--recovery-target-timeline=timeline
```

Specifies a particular timeline to be used for recovery:

- `current` — the timeline of the specified backup, default.
- `latest` — the timeline of the latest available backup.
- A numeric value.

`--recovery-target-lsn=lsn`

Specifies the LSN of the write-ahead log location up to which recovery will proceed.

`--recovery-target-name=recovery_target_name`

Specifies a named savepoint up to which to restore the cluster.

`--recovery-target-time=time`

Specifies the timestamp up to which recovery will proceed. If the time zone offset is not specified, the local time zone is used.

Example: `--recovery-target-time="2027-04-09 18:21:32+00"`

`--recovery-target-xid=xid`

Specifies the transaction ID up to which recovery will proceed.

`--recovery-target-inclusive=boolean`

Specifies whether to stop just after the specified recovery target (`true`), or just before the recovery target (`false`). This option can only be used together with `--recovery-target-time`, `--recovery-target-lsn` or `--recovery-target-xid` options. The default depends on the [recovery\\_target\\_inclusive](#) parameter.

`--recovery-target-action=pause|promote|shutdown`

Specifies [recovery\\_target\\_action](#) the server should take when the recovery target is reached.

Default: `pause`

## Retention Options

You can use these options together with [backup](#) and [delete](#) commands.

For details on configuring retention policy, see the section [Configuring Retention Policy](#).

`--retention-redundancy=redundancy`

Specifies the number of full backup copies to keep in the data directory. Must be a non-negative integer. The zero value disables this setting.

Default: `0`

`--retention-window=window`

Number of days of recoverability. Must be a non-negative integer. The zero value disables this setting.

Default: `0`

`--wal-depth=wal_depth`

Number of latest valid backups on every timeline that must retain the ability to perform PITR. Must be a non-negative integer. The zero value disables this setting.

Default: `0`

`--delete-wal`

Deletes WAL files that are no longer required to restore the cluster from any of the existing backups.

`--delete-expired`

Deletes backups that do not conform to the retention policy defined in the `pg_probackup.conf` configuration file.

`--merge-expired`

Merges the oldest incremental backup that satisfies the requirements of retention policy with its parent backups that have already expired.

`--dry-run`

Displays the current status of all the available backups, without deleting or merging expired backups, if any.

### Pinning Options

You can use these options together with [backup](#) and [set-backup](#) commands.

For details on backup pinning, see the section [Backup Pinning](#).

`--ttl=ttl`

Specifies the amount of time the backup should be pinned. Must be a non-negative integer. The zero value unpins the already pinned backup. Supported units: ms, s, min, h, d (s by default).

Example: `--ttl=30d`

`--expire-time=time`

Specifies the timestamp up to which the backup will stay pinned. Must be an ISO-8601 compliant timestamp. If the time zone offset is not specified, the local time zone is used.

Example: `--expire-time="2027-04-09 18:21:32+00"`

### Logging Options

You can use these options with any command.

`--no-color`

Disable coloring for console log messages of `warning` and `error` levels.

`--log-level-console=log_level`

Controls which message levels are sent to the console log. Valid values are `verbose`, `log`, `info`, `warning`, `error` and `off`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The `off` level disables console logging.

Default: `info`

### Note

All console log messages are going to `stderr`, so the output of [show](#) and [show-config](#) commands does not mingle with log messages.

`--log-level-file=log_level`

Controls which message levels are sent to a log file. Valid values are `verbose`, `log`, `info`, `warning`, `error`, and `off`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The `off` level disables file logging.

Default: `off`

`--log-filename=log_filename`

Defines the filenames of the created log files. The filenames are treated as a `strftime` pattern, so you can use `%`-escapes to specify time-varying filenames.

Default: `pg_probackup.log`

For example, if you specify the `pg_probackup-%u.log` pattern, `pg_probackup` generates a separate log file for each day of the week, with `%u` replaced by the corresponding decimal number: `pg_probackup-1.log` for Monday, `pg_probackup-2.log` for Tuesday, and so on.

This option takes effect if file logging is enabled by the `--log-level-file` option.

`--error-log-filename=error_log_filename`

Defines the filenames of log files for error messages only. The filenames are treated as a `strftime` pattern, so you can use %-escapes to specify time-varying filenames.

Default: none

For example, if you specify the `error-pg_probackup-%u.log` pattern, `pg_probackup` generates a separate log file for each day of the week, with `%u` replaced by the corresponding decimal number: `error-pg_probackup-1.log` for Monday, `error-pg_probackup-2.log` for Tuesday, and so on.

This option is useful for troubleshooting and monitoring.

`--log-directory=log_directory`

Defines the directory in which log files will be created. You must specify the absolute path. This directory is created lazily, when the first log message is written.

Note that the directory for log files is always created locally even if backups are created in the S3 storage. So be sure to pass a local path in `log_directory` when needed.

Default: `$BACKUP_PATH/log/`

`--log-format-console=log_format`

Defines the format of the console log. Only set from the command line. Note that you cannot specify this option in the `pg_probackup.conf` configuration file through the `set-config` command and that the `backup` command also treats this option specified in the configuration file as an error. Possible values are:

- `plain` — sets the plain-text format of the console log.
- `json` — sets the JSON format of the console log.

Default: `plain`

`--log-format-file=log_format`

Defines the format of log files used. Possible values are:

- `plain` — sets the plain-text format of log files.
- `json` — sets the JSON format of log files.

Default: `plain`

`--log-rotation-size=log_rotation_size`

Maximum size of an individual log file. If this value is reached, the log file is rotated once a `pg_probackup` command is launched, except `help` and `version` commands. The zero value disables size-based rotation. Supported units: kB, MB, GB, TB (kB by default).

Default: 0

`--log-rotation-age=log_rotation_age`

Maximum lifetime of an individual log file. If this value is reached, the log file is rotated once a `pg_probackup` command is launched, except `help` and `version` commands. The time of the last log file creation is stored in `$BACKUP_PATH/log/log_rotation`. The zero value disables time-based rotation. Supported units: ms, s, min, h, d (min by default).

Default: 0

### Connection Options

You can use these options together with [backup](#), [catchup](#), and [checkdb](#) commands.

All [libpq environment variables](#) are supported.

`-d dbname`  
`--pgdatabase=dbname`  
PGDATABASE

Specifies the name of the database to connect to. The connection is used only for managing backup process, so you can connect to any existing database. If this option is not provided on the command line, PGDATABASE environment variable, or the `pg_probackup.conf` configuration file, `pg_probackup` tries to take this value from the PGUSER environment variable, or from the current user name if PGUSER variable is not set.

`-h host`  
`--pghost=host`  
PGHOST

Specifies the host name of the system on which the server is running. If the value begins with a slash, it is used as a directory for the Unix domain socket.

Default: localhost

`-p port`  
`--pgport=port`  
PGPORT

Specifies the TCP port or the local Unix domain socket file extension on which the server is listening for connections.

### Warning

The port in PGDATA must match the `--pgport` option value passed via the configuration file, environment variable, or command line. Otherwise, the operation will fail with an error. If necessary, use the `--force` flag to override this check.

Default: 5432

`-U username`  
`--pguser=username`  
PGUSER

User name to connect as.

`-w`  
`--no-password`

Disables a password prompt. If the server requires password authentication and a password is not available by other means such as a [.pgpass](#) file or PGPASSWORD environment variable, the connection attempt will fail. This flag can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Forces a password prompt. (Deprecated)

### Compression Options

You can use these options together with [backup](#) and [archive-push](#) commands.

`--compress-algorithm=compression_algorithm`

Defines the algorithm to use for compressing data files. Possible values are `zlib`, `lz4`, `zstd`, `pglz`, and `none`. If set to any value, but `none`, this option enables compression that uses the corresponding algorithm. Both data files and WAL files are compressed. By default, compression is disabled. For the [archive-push](#) command, the `pglz` compression algorithm is not supported.

### Note

`pg_probackup` supports compression algorithms included in the Postgres Pro version. In particular:

- `lz4` is supported for Postgres Pro Enterprise 13 and higher.
- `zstd` is supported for Postgres Pro Enterprise 11 and higher.

Default: `none`

`--compress-level=compression_level`

Defines the compression level. This option can be used together with the `--compress-algorithm` option. Possible values depend on the compression algorithm specified:

- 0 — 9 for `zlib`
- 1 for `pglz`
- 0 — 12 for `lz4`
- -131072 — 22 for `zstd`

The value of 0 sets the default compression level, which is 1, for all compression algorithms.

### Note

The pure `lz4` algorithm has only one compression level — 1. So, if the specified compression algorithm is `lz4` and `--compress-level` is greater than 1, the `lz4hc` algorithm is actually used, which is much slower although does better compression.

Default: 1

`--compress`

Specifies the default compression algorithm and `--compress-level=1`. The default algorithm is selected among those supported by Postgres Pro according to the priorities: `zstd` (highest) -> `lz4` -> `zlib` -> `pglz`. The `--compress` option overrides the `--compression-algorithm` and `--compress-level` settings and cannot be specified together with them.

## Archiving Options

These options can be used with the [archive-push](#) command in the [archive\\_command](#) setting and the [archive-get](#) command in the [restore\\_command](#) setting.

Additionally, [remote mode options](#) and [logging options](#) can be used.

`--wal-file-path=wal_file_path`

Provides the path to the WAL file in `archive_command` and `restore_command`. Use the `%p` variable as the value for this option or explicitly specify the path to a file outside of the data directory. If you skip this option, the path specified in `pg_probackup.conf` will be used.

`--wal-file-name=wal_file_name`

Provides the name of the WAL file in `archive_command` and `restore_command`. Use the `%f` variable as the value for this option for correct processing. If the value of `--wal-file-path` is a path outside of the data directory, explicitly specify the filename.

`--overwrite`

Overwrites archived WAL file. Use this flag together with the [archive-push](#) command if the specified subdirectory of the backup catalog already contains this WAL file and it needs to be replaced with its newer copy. Otherwise, `archive-push` reports that a WAL segment already exists, and aborts the operation. If the file to replace has not changed, `archive-push` skips this file regardless of the `--overwrite` flag.

`--batch-size=batch_size`

Used to speed up archiving in case of `archive-push` or to speed up recovery in case of `archive-get`. Sets the maximum number of WAL files that can be copied into the archive by a single `archive-push` process, or from the archive by a single `archive-get` process.

`--archive-timeout=wait_time`

Sets the timeout for considering existing `.part` files to be stale. By default, `pg_probackup` waits 300 seconds. This option can be used only with [archive-push](#) command.

`--no-ready-rename`

Do not rename status files in the `archive_status` directory. This option should be used only if `archive_command` contains multiple commands. This option can be used only with [archive-push](#) command.

`--no-sync`

Do not sync copied WAL files to disk. You can use this flag to speed up archiving process. Using this flag can result in WAL archive corruption in case of operating system or hardware crash. This option can be used only with [archive-push](#) command.

`--prefetch-dir=path`

Directory used to store prefetched WAL segments if `--batch-size` option is used. Directory must be located on the same filesystem and on the same mountpoint the `PGDATA/pg_wal` is located. By default files are stored in `PGDATA/pg_wal/pbk_prefetch` directory. This option can be used only with [archive-get](#) command.

`--no-validate-wal`

Do not validate prefetched WAL file before using it. Use this option if you want to increase the speed of recovery. This option can be used only with [archive-get](#) command.

### Remote Mode Options

This section describes the options related to running `pg_probackup` operations remotely via SSH. These options can be used with [add-instance](#), [set-config](#), [backup](#), [catchup](#), [restore](#), [archive-push](#), and [archive-get](#) commands.

For details on configuring and using the remote mode, see [the section called “Configuring the Remote Mode”](#) and [the section called “Using pg\\_probackup in the Remote Mode”](#).

`--remote-proto=proto`

Specifies the protocol to use for remote operations. Currently only the SSH protocol is supported. Possible values are:

- `ssh` enables the remote mode via SSH. This is the default value.

- `none` explicitly disables the remote mode.

You can omit this option if the `--remote-host` option is specified.

`--remote-host=destination`

Specifies the remote host IP address or hostname to connect to.

`--remote-port=port`

Specifies the remote host port to connect to.

Default: 22

`--remote-user=username`

Specifies remote host user for SSH connection. If you omit this option, the current user initiating the SSH connection is used.

`--remote-path=path`

Specifies `pg_probackup` installation directory on the remote system.

`--ssh-options=ssh_options`

Provides a string of SSH command-line options. For example, the following options can be used to set `keep-alive` for SSH connections opened by `pg_probackup`: `--ssh-options="-o ServerAliveCountMax=5 -o ServerAliveInterval=60"`. For the full list of possible options, see [ssh\\_config manual page](#).

### Remote WAL Archive Options

This section describes the options used to provide the arguments for [remote mode options](#) in `archive-get` used in the `restore_command` command when restoring ARCHIVE backups or performing PITR.

`--archive-host=destination`

Provides the argument for the `--remote-host` option in the `archive-get` command.

`--archive-port=port`

Provides the argument for the `--remote-port` option in the `archive-get` command.

Default: 22

`--archive-user=username`

Provides the argument for the `--remote-user` option in the `archive-get` command. If you omit this option, the user that has started the Postgres Pro cluster is used.

Default: Postgres Pro user

### Incremental Restore Options

This section describes the options for incremental cluster restore. These options can be used with the `restore` command.

`-I incremental_mode`

`--incremental-mode=incremental_mode`

Specifies the incremental mode to be used. Possible values are:

- `CHECKSUM` — replace only pages with mismatched checksum and LSN.
- `LSN` — replace only pages with LSN greater than point of divergence.
- `NONE` — regular restore.

### Partial Restore Options

This section describes the options for partial cluster restore. These options can be used with the [restore](#) command.

`--db-exclude=dbname`

Specifies the name of the database to exclude from restore. All other databases in the cluster will be restored as usual, including `template0` and `template1`. This option can be specified multiple times for multiple databases.

`--db-include=dbname`

Specifies the name of the database to restore from a backup. All other databases in the cluster will not be restored, with the exception of `template0` and `template1`. This option can be specified multiple times for multiple databases.

### S3 Options

This section describes the options needed to store backups in private clouds. These options can be used with any commands that `pg_probackup` runs using S3 interface.

`--s3=s3_interface_provider`

Specifies the S3 interface provider. Possible values are:

- `minio` — MinIO object storage, compatible with S3 cloud storage service. With this provider, custom S3 server settings can be specified. The HTTP protocol, port 9000, and region `us-east-1` are used by default.
- `vk` — VK Cloud storage. With this provider, the S3 host address `hb.vkcs.cloud`, port 443, and HTTPS protocol are only used. Custom values of the host, port, and protocol are ignored. The default value of region is `ru-msk`.
- `aws` — Amazon S3 storage, offered by Amazon Web Services (AWS). With this provider, the S3 host address `bucket_name.s3.region.amazonaws.com`, port 443, and HTTPS protocol are only used. Custom values of the host, port, and protocol are ignored. The default value of region is `us-east-1`.

With `--s3=minio`, `pg_probackup` will work fine for a VK Cloud storage if the S3 host address, port and protocol are properly specified (host address is `hb.vkcs.cloud` or the one specified in the appropriate section of the VK Cloud profile, port 443, and HTTPS protocol). Do not specify `--s3=minio` for the Amazon S3 storage.

Once a `pg_probackup` command runs with the `--s3` option, `pg_probackup` starts running all commands that support parallel execution on 10 parallel threads (for details, see [the section called “Running pg\\_probackup on Parallel Threads”](#)). You can change the number of threads using the `-j/--threads` option.

`--s3-config-file=path_to_config_file`

Specifies the S3 configuration file. Settings in the configuration file override the environment variables. If this option is not specified, `pg_probackup` first looks for the S3 configuration file at `/etc/pg_probackup/s3.config` and then at `~postgres/.pg_probackup/s3.config`. The following is an example of the S3 configuration file:

```
access-key = ...
secret-key = ...
s3-host = localhost
s3-port = 9000
s3-bucket = s3demo
s3-region=us-east-1
s3-buffer-size = 32
s3-secure = on | https | http | off
```

## Testing and Debugging Options

This section describes options useful only in a test or development environment.

`--cfs-nondatfile-mode`

Instructs `backup` command to backup CFS in a legacy mode. This allows fine-tuning compatibility with `pg_probackup` versions earlier than 2.6.0. This option is mainly designed for testing.

`PGPROBACKUP_TESTS_SKIP_HIDDEN`

Instructs `pg_probackup` to ignore backups marked as hidden. Note that `pg_probackup` can never mark a backup as hidden. It can only be done by directly editing the `backup.control` file. This option can only be set with environment variables.

`--destroy-all-other-dbs`

By default, `pg_probackup` exits with an error if an attempt is made to perform a partial incremental restore since this destroys databases not included in the restore set. This flag allows you to suppress the error and proceed with the partial incremental restore (e.g., to keep a development database snapshot up-to-date with a production one). This option can be used with the `restore` command.

### Important

Never use this flag in a production cluster.

`--lock-lifetime`

Specifies the lifetime for locks taken when performing a backup, in seconds. The default value is 300. The minimum value is 60.

`PGPROBACKUP_TESTS_SKIP_EMPTY_COMMIT`

Instructs `pg_probackup` to skip empty commits after `pg_backup_stop`.

## Versioning

`pg_probackup` follows *semantic* versioning.

## Authors

Postgres Professional, Moscow, Russia.

## Credits

`pg_probackup` utility is based on `pg_arman`, which was originally written by NTT and then developed and maintained by Michael Paquier.

## vacuumlo

`vacuumlo` — remove orphaned large objects from a Postgres Pro database

### Synopsis

```
vacuumlo [option...] dbname...
```

### Description

`vacuumlo` is a simple utility program that will remove any “orphaned” large objects from a Postgres Pro database. An orphaned large object (LO) is considered to be any LO whose OID does not appear in any `oid` or `lo` data column of the database.

If you use this, you may also be interested in the `lo_manage` trigger in the [lo](#) module. `lo_manage` is useful to try to avoid creating orphaned LOs in the first place.

All databases named on the command line are processed.

### Options

`vacuumlo` accepts the following command-line arguments:

```
-l limit
--limit=limit
```

Remove no more than *limit* large objects per transaction (default 1000). Since the server acquires a lock per LO removed, removing too many LOs in one transaction risks exceeding [max\\_locks\\_per\\_transaction](#). Set the limit to zero if you want all removals done in a single transaction.

```
-n
--dry-run
```

Don't remove anything, just show what would be done.

```
-v
--verbose
```

Write a lot of progress messages.

```
-V
--version
```

Print the `vacuumlo` version and exit.

```
-?
--help
```

Show help about `vacuumlo` command line arguments, and exit.

`vacuumlo` also accepts the following command-line arguments for connection parameters:

```
-h host
--host=host
```

Database server's host.

```
-p port
--port=port
```

Database server's port.

```
-U username
--username=username
```

User name to connect as.

```
-w
--no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W
--password
```

Force vacuumlo to prompt for a password before connecting to a database.

This option is never essential, since vacuumlo will automatically prompt for a password if the server demands password authentication. However, vacuumlo will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

## Environment

```
PGHOST
PGPORT
PGUSER
```

Default connection parameters.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 36.15](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

vacuumlo works by the following method: First, vacuumlo builds a temporary table which contains all of the OIDs of the large objects in the selected database. It then scans through all columns in the database that are of type `oid` or `lo`, and removes matching entries from the temporary table. (Note: Only types with these names are considered; in particular, domains over them are not considered.) The remaining entries in the temporary table identify orphaned LOs. These are removed.

## I.2. Third-Party Client Applications

This section covers third-party client applications included in the Postgres Pro Enterprise distribution. They can be run from anywhere, independent of where the database server resides.

## pgbadger

pgbadger — rapidly analyze Postgres Pro logs, producing detailed reports and graphs

### Synopsis

```
pgbadger [connection-option...] [option...] [logfile...]
```

### Description

pgbadger is a Postgres Pro/PostgreSQL log analyzer, which rapidly provides detailed reports based on your log files. pgbadger is provided with Postgres Pro as a standalone Perl script.

*logfile* can be a single log file, a list of files or a shell command that returns a list of files. To get log content from the standard input, pass “-” as *logfile*.

pgbadger can parse huge log files and compressed files. It can autodetect your log file format (syslog, stderr, csvlog or jsonlog) if the file is long enough. Supported compressed formats are gzip, bzip2, lz4, xz, zip and zstd. For the xz format, you must have an xz version higher than 5.05, which supports the `--robot` option. For pgbadger to determine the uncompressed file size for the lz4 format, the file must be compressed with the `--content-size` option.

pgbadger supports any format of log-line prefixes that can be specified through the [log\\_line\\_prefix](#) configuration setting of your `postgresql.conf` configuration file, provided that at least `%t` and `%p` are specified.

[pgbouncer](#) log files can also be parsed.

To speed up log parsing, you can use any of these multiprocessing modes: one core per log file and multiple cores per file. These modes can be combined.

pgbadger can also parse remote log files fetched using a passwordless SSH connection. This mode can be used with compressed files and even supports multiprocessing with multiple cores per file.

Examples of reports can be found at <https://pgbadger.darold.net/#reports>.

### Limitations

pgbadger currently has the following limitations:

- Multiprocessing is not supported for compressed log files and CSV files, as well as on Windows.
- CSV format of log files cannot be parsed remotely.
- csvlog logs cannot be passed from the standard input.

### Setup and Configuring

pgbadger is provided with Postgres Pro Enterprise as a separate pre-built package `pgbadger` (for the detailed installation instructions, see [Chapter 17](#)). Once you have pgbadger installed, complete the setup described in sections below.

#### [Optional] Set up Parsing Specific Log Formats

If you plan to parse CSV log files, install `Text::CSV_XS` Perl module.

#### [Optional] Set up Export of Statistics

If you want to export statistics as a JSON file, install `JSON::XS` Perl module:

To install this optional module:

- On a Debian-based system, run:

```
sudo apt-get install libjson-xs-perl
```

- On an RPM system, run:

```
sudo yum install perl-JSON-XS
```

### [Optional] Set up Parsing Compressed Log Files

By default, pgbadger autodetects the compressed log file format from the file extension and uses decompression utilities accordingly:

- `zcat` for `gz`
- `bzcat` for `bz2`
- `lz4cat` for `lz4`
- `zstdcat` for `zst`
- `unzip` or `xz` for `zip` or `xz`

If the needed utility is outside of your `PATH` directories, use the `--zcat` command-line option to specify the path to the decompression utility. For example:

```
--zcat="/usr/local/bin/gunzip -c" or --zcat="/usr/local/bin/bzip2 -dc"  
--zcat="C:\tools\unzip -p"
```

### Note

With the default autodetection of the compressed file format, you can mix `gz`, `bz2`, `lz4`, `xz`, `zip` and `zstd` log files. Once you specified a custom value of `--zcat`, mixing compressed files of different formats is longer possible.

## Configure Your Postgres Pro Server

Set the values of certain configuration parameters in your `postgresql.conf`:

- Set up logging SQL queries.

To enable SQL query logging and have the query statistics include actual query strings, set

```
log_min_duration_statement = 0
```

On a busy server you may want to increase this value to only log queries with a longer duration.

If you just want to report the duration and number of queries and do not want details of queries, set `log_min_duration_statement` to `-1`, which disables logging statement durations, and enable `log_duration`.

Enabling `log_min_duration_statement` will add reports about slowest queries and queries that took the most time. Note that if you set `log_statement` to `all`, the setting of `log_min_duration_statement` will have no effect.

### Warning

Avoid setting `log_min_duration_statement` to a non-positive value together with enabling `log_duration` and `log_statement` as this will result in wrong counter values and drastically increase the size of your log. Always prefer setting `log_min_duration_statement`.

- Set the log line prefix string in `log_line_prefix`.

It must at least include a time escape sequence (`%t`, `%m` or `%n`) and the process-related escape sequence (`%p` or `%c`). For example, for `stderr` logs, the setting must be at least

```
log_line_prefix = '%t [%p]: '
```

The log line prefix could also specify the user, database name, application name and client IP address. For example,

for stderr logs:

```
log_line_prefix = '%t [%p]: user=%u,db=%d,app=%a,client=%h '
```

or

```
log_line_prefix = '%t [%p]: db=%d,user=%u,app=%a,client=%h '
```

and for syslog logs:

```
log_line_prefix = 'user=%u,db=%d,app=%a,client=%h '
```

or

```
log_line_prefix = 'db=%d,user=%u,app=%a,client=%h '
```

- To get more information from your log files, set certain configuration parameters as follows:

```
log_checkpoints = on
log_connections = on
log_disconnections = on
log_lock_waits = on
log_temp_files = 0
log_autovacuum_min_duration = 0
log_error_verbosity = default
```

To benefit from these settings, do not enable [log\\_statement](#) as pgbadger does not parse the corresponding log format.

- Set the language in which messages are displayed; messages must be in English with or without locale support:

```
lc_messages='C'
```

or

```
lc_messages='en_US.UTF-8'
```

Locales for other languages, such as `ru_RU.utf8`, are not supported.

## Usage

The following are simple examples to illustrate miscellaneous pgbadger usage details.

```
pgbadger /var/lib/pgpro/ent-14/data/log/postgresql-2022-01-14_000000.log
pgbadger /var/lib/pgpro/ent-14/data/log/postgres.log.2.gz /var/lib/pgpro/ent-14/data/
log/postgres.log.1.gz /var/lib/pgpro/ent-14/data/log/postgresql-2022-01-14_000000.log
pgbadger /var/lib/pgpro/ent-14/data/log/postgresql/postgresql-2022-01-*
pgbadger --exclude-query="^(COPY|COMMIT)" /var/lib/pgpro/ent-14/data/log/
postgresql-2022-01-14_000000.log
pgbadger -b "2022-01-25 10:56:11" -e "2022-01-25 10:59:11" /var/lib/pgpro/ent-14/data/
log/postgresql-2022-01-25-0000.log
cat /var/lib/pgpro/ent-14/data/log/postgresql-2022-01-14_000000.log | pgbadger -
# Log line prefix with stderr log output
pgbadger --prefix '%t [%p]: user=%u,db=%d,client=%h' /var/lib/pgpro/ent-14/data/log/
postgresql-2022-08-21*
pgbadger --prefix '%m %u@d %p %r %a : ' /var/lib/pgpro/ent-14/data/log/
postgresql-2022-08-21-0000.log
# Log line prefix with syslog log output
pgbadger --prefix 'user=%u,db=%d,client=%h,appname=%a' /var/lib/pgpro/ent-14/data/log/
postgresql-2022-08-21*
# Use 8 CPUs to parse 10GB file faster
```

```
pgbadger -j 8 /var/lib/pgpro/ent-14/data/log/postgresql-2022-08-21-0000.log
# Use a cron job to report errors weekly
30 23 * * 1 /usr/bin/pgbadger -q -w /var/lib/pgpro/ent-14/data/log/
postgresql-2022-01*.log -o /var/www/pg_reports/pg_errors.html
```

## Specifying Remote Log Files

Specify remote log files to parse using a URI. Supported protocols are HTTP[S] and [S]FTP. The `curl` command will be used to download the file, and the file will be parsed during download. The SSH protocol is also supported and will use the `ssh` command to get log files, as when the `--remote-host` option is used.

Use these URI notations for the remote log file:

```
pgbadger http://172.12.110.1//var/lib/pgpro/ent-14/data/log/
postgresql-2022-01-14_000000.log
pgbadger ftp://username@172.12.110.14/postgresql-2022-01-14_000000.log
pgbadger ssh://username@172.12.110.14:2222//var/lib/pgpro/ent-14/data/log/
postgresql-2022-01-14_000000.log*
```

You can parse a local Postgres Pro log and a remote [pgbouncer](#) log file together:

```
pgbadger /var/lib/pgpro/ent-14/data/log/postgresql-2022-01-14_000000.log ssh://
username@172.12.110.14/pgbouncer.log
```

## Parallel Processing

To enable parallel processing, specify the `-j N` option, where *N* is the number of cores to use.

Parallel processing in `pgbadger` follows the algorithm below:

```
For each log file
  chunk size = int(file size / N)
  look at start/end offsets of these chunks
  fork N processes and seek to the start offset of each chunk
    each process will terminate when the parser reaches the end offset of its chunk
    each process writes stats into a binary temporary file
  wait for all child processes to terminate
All binary temporary files generated will then be read and loaded into
memory to build the html output.
```

With this method, at start/end of chunks `pgbadger` may truncate or omit a maximum of *N* queries per log file, which is an insignificant gap if you have millions of queries in your log file. The chance that the query that you were looking for is lost is near zero, so this gap can be considered suitable. Most of the time the query is counted twice, but truncated.

When you have many small log files and many CPUs, it is faster to dedicate one core to one log file at a time. To enable this behavior, specify the `-J N` option instead. Using this method, you can be sure not to lose any queries in the reports. With 200 log files of 10 MB each, the `-J` option starts being really efficient with 8 cores.

Here is a benchmark done on a server with 8 CPUs and a single file of 9.5 GB.

| Option | 1 CPU   | 2 CPU | 4 CPU | 8 CPU |
|--------|---------|-------|-------|-------|
| -j     | 1h41m18 | 50m25 | 25m39 | 15m58 |
| -J     | 1h41m18 | 54m28 | 41m16 | 34m45 |

With 200 log files of 10 MB each, which is 2 GB in total, the results are slightly different:

| Option | 1 CPU   | 2 CPU | 4 CPU | 8 CPU |
|--------|---------|-------|-------|-------|
| -j     | 1h41m18 | 50m25 | 25m39 | 15m58 |
| -J     | 1h41m18 | 54m28 | 41m16 | 34m45 |

```
-j      | 20m15 | 9m56 | 5m20 | 4m20  
-J      | 20m15 | 9m49 | 5m00 | 2m40
```

So it is recommended to use the `-j` option unless you have hundreds of small log files and can use at least 8 CPUs.

### Important

During parallel parsing, `pgbadger` generates a lot of temporary files named `tmp_pgbadgerXXXX.bin` in the `/tmp` directory and removes them at the end.

## Building Incremental Reports

The following sample cron job builds a report every week with the incremental behavior assuming that your log file and HTML report are also rotated every week:

```
0 4 * * 1 /usr/bin/pgbadger -q `find /var/lib/pgpro/ent-14/data/log/ -mtime -7 -name  
"postgresql.log*"` -o /var/www/pg_reports/pg_errors-`date +%F`.html -l /var/reports/  
pgbadger_incremental_file.dat
```

But better turn on `pgbadger`'s automatic building incremental reports by specifying the `-I/--incremental` option. In this mode, `pgbadger` builds one report per day and a cumulative report per week. The output is first built in the binary format and saved to the output directory, specified by the `-O/--outdir` option, and then daily and weekly reports are built in the HTML format with the main index file. The main index file shows a dropdown menu per week with a link to the week's report and links to daily reports for that week. For example, run `pgbadger` as follows with the file rotated daily:

```
0 4 * * * /usr/bin/pgbadger -I -q /var/lib/pgpro/ent-14/data/log/postgresql/  
postgresql.log.1 -O /var/www/pg_reports/
```

You will have all daily and weekly reports. In this mode `pgbadger` will automatically create an incremental file in the output directory, so you do not have to use the `-l` option unless you want to change the path of that file. This means that you can run `pgbadger` in this mode every day on a log file rotated every week and it will not count the log entries twice. To save disk space, you may want to use the `-x/--extra-files` command-line option to force `pgbadger` to write CSS and JavaScript files to the output directory as separate files. The resources will then be loaded using script and link tags.

In the incremental mode, you can also specify the number of weeks to keep in the report by using the `-O/--retention` option:

```
/usr/bin/pgbadger --retention 2 -I -q /var/lib/pgpro/ent-14/data/log/postgresql/  
postgresql.log.1 -O /var/www/pg_reports/
```

If `pg_dump` is scheduled to run at 23:00 and 13:00 every day, you can exclude these periods from the report as follows:

```
pgbadger --exclude-time "2013-09-.* (23|13):.*" postgresql.log
```

This will help avoid having `COPY` statements generated by `pg_dump` on top of the list of slowest queries. Alternatively, you can use `--exclude-appname "pg_dump"` to solve this problem in a simpler way.

## Rebuilding Reports

To update all HTML reports after fixing a `pgbadger` report or adding a new feature to it, you can rebuild incremental reports. To rebuild all reports in the case a binary file is still available, run:

```
rm /path/to/reports/*.js  
rm /path/to/reports/*.css  
pgbadger -X -I -O /var/www/pg_reports/ --rebuild
```

This will also update all the resource files (JavaScript and CSS). Use the `-E/--explode` option if the reports were built with this option.

### Building Monthly Reports

By default, in the incremental mode pgbadger only computes daily and weekly reports. To have monthly cumulative reports, you will need to use a separate command to specify the report to build. For example, to build a report for August 2021, run:

```
pgbadger -X --month-report 2021-08 /var/www/pg_reports/
```

This will add a link to the month name to the calendar view of incremental reports to look at the monthly report. The report for a current month can be run every day, and it is entirely rebuilt each time. The monthly report is not built by default because it could take too long. Like when rebuilding reports, if reports were built with the per-database option (`-E/--explode`), it must be used to build the monthly report:

```
pgbadger -E -X --month-report 2021-08 /var/www/pg_reports/
```

### Choosing the Report File Format

The pgbadger report file format is determined by the extension of the file passed to the `-o/--outfile` option.

Use the binary format (`-o *.bin`) to create custom incremental and cumulative reports.

For example, to refresh a pgbadger report every hour from a daily log file, you can run the following commands every hour:

```
# Generate incremental data files in the binary format
pgbadger --last-parsed .pgbadger_last_state_file -o sunday/hourX.bin /var/lib/pgpro/
ent-14/data/log/postgresql-Sun.log
# Build a fresh HTML report from the generated binary file
pgbadger sunday/*.bin
```

For another example, assume that you generate one log file per hour. To have reports rebuilt each time the log file is rotated, run:

```
pgbadger -o day1/hour01.bin /var/lib/pgpro/ent-14/data/log/postgresql-2022-01-23_10.log
pgbadger -o day1/hour02.bin /var/lib/pgpro/ent-14/data/log/postgresql-2022-01-23_11.log
pgbadger -o day1/hour03.bin /var/lib/pgpro/ent-14/data/log/postgresql-2022-01-23_12.log
...
```

And to refresh the HTML report, for example, each time after a new binary file is generated, just run:

```
pgbadger -o day1_report.html day1/*.bin
```

Adjust the commands to your particular needs.

Use the JSON format (`-o *.json`) to share data with other languages and to facilitate integration of pgbadger output with other monitoring tools, such as Cacti or Graphite.

Select other output formats to meet your particular needs. For example, this command will generate *Tsung* sessions XML file for `SELECT` queries only:

```
pgbadger -S -o sessions.tsung --prefix '%t [%p]: user=%u,db=%d ' /var/lib/pgpro/
ent-14/data/log/postgresql-2022-01-14_000000.log
```

### Return Codes

pgbadger return codes depend on how it terminated as follows:

- 0: was a success
- 1: died on error
- 2: has been interrupted using `Ctrl+C`, for example
- 3: the PID file already exists or cannot be created

- 4: no log file was specified on the command line

## Options

This section describes pgbadger command-line options.

`-a minutes`

`--average minutes`

Specifies the number of minutes for which to build average graphs of queries and connections.

Default: 5.

`-A minutes`

`--histo-average minutes`

Specifies the number of minutes for which to build histogram graphs of queries.

Default: 60.

`-b datetime`

`--begin datetime`

Timestamp or time that specifies the start date/time for the data to be parsed in logs.

`-c host`

`--dbclient host`

Only report on log entries for the specified client host.

`-C`

`--nocomment`

Remove `/* ... */` comments from queries.

`-d name`

`--dbname name`

Only report on log entries for the specified database.

`-D`

`--dns-resolv`

Replace client IP addresses with their DNS names.

### Warning

This can considerably slow down pgbadger.

`-e datetime`

`--end datetime`

Timestamp or time that specifies the end date/time for the data to be parsed in logs.

`-E`

`--explode`

Build one report per each database. Global information not related to any database gets added to the postgres database report.

`-f logtype`

`--format logtype`

Specifies the log type.

**Possible values:** syslog, syslog2, stderr, jsonlog, csv, pgbouncer, logplex, rds and redshift. Use when pgbadger cannot detect the log format.

- G  
--nograph  
Disables graphs in HTML output.
- h  
--help  
Show detailed information about pbadger options and exit.
- H *path*  
--html-outdir *path*  
Specifies the path to the directory where the HTML report must be written in the incremental mode. Note that binary files remain in the directory specified by -O/--outdir.
- i *name*  
--ident *name*  
Specifies the program name used to identify Postgres Pro messages in syslog logs.  
Default: postgres.
- I  
--incremental  
Use the incremental mode, where reports will be generated by days in a separate directory specified by the -O/--outdir option.
- j *number*  
--jobs *number*  
Specifies the number of jobs to run at the same time. When working with csvlog logs, pgbadger always runs as single job.  
Default: 1.
- J *number*  
--Jobs *number*  
Specifies the number of log files to parse in parallel.  
Default: 1.
- l *filename*  
--last-parsed *filename*  
Specifies the file where the last datetime and line parsed are registered to allow incremental log parsing. Useful to watch errors since the last run or to get one report per day with the log rotated weekly.
- L *filename*  
--logfile-list *filename*  
Specifies the file containing the list of log files to parse.
- m *size*  
--maxlength *size*  
Specifies the maximum length of a query in reports. Longer queries will be truncated.

Default: 100000.

`-M`  
`--no-multiline`

Turns off collecting multiline statements to avoid reporting excessive information, especially on errors that generate a huge report.

`-N name`  
`--appname name`

Only report on log entries for the specified application.

`-o filename`  
`--outfile filename`

Specifies the filename for the output and determines the report file format: `out.html`, `out.txt`, `out.bin` or `out.json`. Can be used multiple times to output several formats. For the `json` output, ensure that the Perl module `JSON::XS` is installed. To dump the output to stdout, use the value of `"-"` as filename.

Default: `out.html`, `out.txt`, `out.bin`, `out.json` or `out.tsung`,  
for the respective output format.

`-O path`  
`--outdir path`

Specifies the directory where out files must be saved.

`-p string`  
`--prefix string`

Specifies the value of your custom `log_line_prefix` string, as defined in your `postgresql.conf`. Only use if your log line prefix is different from the standard `log_line_prefix` strings, for example, if your prefix includes additional variables, such as client IP or application name. The string must contain escape sequences for time (`%t`, `%m` or `%n`) and processes (`%p` or `%c`).

`-P`  
`--no-prettify`

Disables SQL query code prettifier.

`-q`  
`--quiet`

Disables printing anything to stdout, even the progress bar.

`-Q`  
`--query-numbering`

Add numbering of queries to the output when used together with `--dump-all-queries` or `--normalized-only`.

`-r address`  
`--remote-host address`

Specifies the host to execute the `cat` command on a remote log file to parse the file locally.

`-R number`  
`--retention number`

Specifies the number of weeks for which to keep reports in the output directory in the incremental mode. The directories for older weeks and days are automatically removed.

Default: 0 (no reports are removed).

`-s number`  
`--sample number`

Specifies the number of query samples to store.

Default: 3.

`-S`  
`--select-only`

Only report on SELECT queries.

`-t number`  
`--top number`

Specifies the number of queries to store/display.

Default: 20.

`-T string`  
`--title string`

Specifies the title of the HTML report page.

`-u username`  
`--dbuser username`

Only report on log entries for the specified username.

`-U username`  
`--exclude-user username`

Specifies the username to exclude log entries for from the report. Can be used multiple times.

`-v`  
`--verbose`

Enables the verbose or debug mode.

Default: off.

`-V`  
`--version`

Show pgbadger version and exit.

`-w`  
`--watch-mode`

Only report errors, just like [Logwatch](#) can do.

`-W`  
`--wide-char`

Encode HTML output of queries in UTF8 to avoid Perl messages “Wide character in print”.

`-x format`  
`--extension format`

Specifies the output format. Possible values: text, html, bin or json.

Default: html.

`-X`  
`--extra-files`  
In the incremental mode, write CSS and JavaScript resources to the output directory as separate files.

`-z command`  
`--zcat command`  
Specifies the full command to run the zcat program. Use if zcat, bzip2 or unzip is outside of your PATH directories.

`-Z +/-XX`  
`--timezone +/-XX`  
Specifies the number of hours from GMT for the timezone. Use to adjust date/time in JavaScript graphs. The value can be an integer (e.g., 2), or a float, (e.g., 2.5).

`--pie-limit number`  
Specifies the number such that instead of lower pie data the sum will be shown.

`--exclude-query regexp`  
Specifies the regular expression such that matching queries will be excluded from the report. For example: “^(VACUUM|COMMIT)”. Can be used multiple times.

`--exclude-file filename`  
Specifies the path to the file that contains each regular expression to use to exclude matching queries from the report, one expression per line.

`--include-query regexp`  
Specifies the regular expression such that only matching queries will be included in the report. Can be used multiple times. For example: “(tbl1|tbl2)”.

`--include-file filename`  
Specifies the path to the file that contains each regular expression to use to include matching queries in the report, one expression per line.

`--disable-error`  
Turns off generation of an error report.

`--disable-hourly`  
Turns off generation of an hourly report.

`--disable-type`  
Turns off generation of a report on queries by type, database and user.

`--disable-query`  
Turns off generation of query reports, such as slowest or most frequent queries, queries by users, by database and so on.

`--disable-session`  
Turns off generation of a session report.

`--disable-connection`  
Turns off generation of a connection report.

`--disable-lock`  
Turns off generation of a lock report.

`--disable-temporary`

Turns off generation of a report on temporary files.

`--disable-checkpoint`

Turns off generation of checkpoint/restartpoint reports.

`--disable-autovacuum`

Turns off generation of an autovacuum report.

`--charset name`

Specifies the HTML charset to be used.

Default: utf-8.

`--csv-separator char`

Specifies the CSV field separator.

Default: “,”.

`--exclude-time regexp`

Specifies the regular expression such that log entries for any matching timestamp will be excluded from the report. For example: “2013-04-12 .\*”. Can be used multiple times.

`--include-time regexp`

Specifies the regular expression such that log entries for any matching timestamp will be included in the report. For example: “2013-04-12 .\*”. Can be used multiple times.

`--exclude-db name`

Specifies the name of the database to exclude related log entries from the report. For example: “outdated\_db”. Can be used multiple times.

`--exclude-appname name`

Specifies the name of the application to exclude related log entries from the report. For example: “pg\_dump”. Can be used multiple time.

`--exclude-line regexp`

Specifies the regular expression such that any matching log entry will be excluded from the report. Can be used multiple times.

`--exclude-client name`

Specifies the client IP/name to exclude related log entries from the report. Can be used multiple times.

`--anonymize`

Obscure all literals in queries. Useful to hide confidential data.

`--noreport`

Prevents generation of reports in the incremental mode.

`--log-duration`

Associate log entries generated by `log_duration = on` and `log_statement = all`.

`--enable-checksum`

Add the MD5 sum under each query report.

`--journalctl command`

Specifies the command to produce the information similar to what the Postgres Pro log file contains. Usually, like this: `journalctl -u postgrespro-ent-14`.

`--pid-dir path`

Specifies the path to store the PID file.

Default: `/tmp`.

`--pid-file filename`

Specifies the name of the PID file to manage concurrent execution of `pgbadger`.

Default: `pgbadger.pid`.

`--rebuild`

Rebuild all HTML reports in incremental output directories that contain binary data files.

`--pgbouncer-only`

Only show [pgbouncer](#)-related menus in the header.

`--start-monday`

In the incremental mode, start calendar weeks on Monday. By default, they start on Sunday.

`--iso-week-number`

In the incremental mode, start calendar weeks on Monday (by default, they start on Sunday) with ISO 8601 week numbering: 01 to 53, where week 1 is the first week of a year that has at least 4 days.

`--normalized-only`

Only dump all normalized queries to `out.txt`.

`--log-timezone +/-XX`

Specifies the number of hours from GMT for the timezone to adjust date/time read from the log file before parsing. The use of this option makes log search with date/time more complicated. The value can be an integer (e.g., 2), or a float, (e.g., 2.5).

`--prettify-json`

Prettify JSON output.

`--month-report YYYY-MM`

Specifies the month (YYYY-MM) to create a cumulative HTML report for. Requires incremental output directories to be set and all the necessary binary data files available.

`--day-report YYYY-MM-DD`

Specifies the day (YYYY-MM-DD) to create an HTML report for. Requires incremental output directories to be set and all the necessary binary data files available.

`--noexplain`

Avoid processing log lines generated by [auto\\_explain](#).

`--command cmd`

Specifies the command to run to retrieve log entries on stdin. `pgbadger` will open a pipe to this command and parse log entries that it generates.

`--no-week`

Avoid building weekly reports in the incremental mode. Use if building weekly reports takes too long.

`--explain-url URL`

Specifies the URL to override the URL of the graphical explain tool.

Default: <http://explain.depesz.com/>

`--tmpdir path`

Specifies the directory for temporary files.

Default: `File::Spec->tmpdir() || '/tmp'`.

`--no-process-info`

Disables changing the pgbadger process title to help identify this process. Useful for systems where changing process titles is not supported.

`--dump-all-queries`

Dump all queries found in the log file to a text file, replacing bind parameters in the queries at their respective placeholder positions.

`--keep-comments`

Retains comments in normalized queries. Useful to distinguish between same normalized queries.

`--no-progressbar`

Disables displaying the progress bar.

`--dump-raw-csv`

Parse the log and dump the information into CSV format. No further processing is done, no report.

`--include-pid PID`

Only report events related to the session PID (%p). Can be used multiple times.

`--include-session ID`

Only report events related to the session ID (%c). Can be used multiple times.

`--histogram-query VAL`

Use custom inbound for query time histogram. Default inbound in milliseconds: 0,1,5,10,25,50,100,500,1000,10000.

`--histogram-session VAL`

Use custom inbound for session time histogram. Default inbound in milliseconds: 0,500,1000,30000,60000,600000,1800000,3600000,28800000.

## Remote Log Connection Options

pgbadger can parse a remote log file fetched using passwordless SSH connection. Use the `-r/--remote-host` option to set the IP address or name of the target host. More options to define SSH connection parameters are as follows:

`--ssh-program ssh`

Specifies the path to the SSH program to use.

Default: `ssh`.

`--ssh-port port`

Specifies the SSH port for the connection.

Default: 22.

`--ssh-user username`

Specifies the username for the connection.

Default: user running pgbadger.

`--ssh-identity filename`

Specifies the path to the identity file.

`--ssh-timeout seconds`

Specifies the timeout in seconds in case of the SSH connection failure.

Default: 10.

`--ssh-option options`

Specifies the list of options to define SSH connection parameters. The following options are always used:

`-o ConnectTimeout=$ssh_timeout -o PreferredAuthentications=hostbased,publickey`

`-o PreferredAuthentications=hostbased,publickey`

## pg\_repack

pg\_repack — utility and Postgres Pro Enterprise extension to reorganize tables

### Synopsis

```
pg_repack [option...] [dbname]
```

### Description

*pg\_repack* is a Postgres Pro Enterprise extension which lets you remove bloat from tables and indexes, and optionally restore the physical order of clustered indexes. Unlike `CLUSTER` and `VACUUM FULL` it works online, without holding an exclusive lock on the processed tables during processing. *pg\_repack* is efficient to boot, with performance comparable to using `CLUSTER` directly.

*pg\_repack* is a fork of the previous [https://github.com/reorg/pg\\_reorg](https://github.com/reorg/pg_reorg) project.

You can choose one of the following methods to reorganize data:

- Online `CLUSTER` (ordered by cluster index)
- Ordering by specified columns
- Online `VACUUM FULL` (packing rows only)
- Rebuild or relocate only the indexes of a table

#### Note

Only superusers can use the utility.

#### Note

Target table must have a PRIMARY KEY, or at least a UNIQUE total index on a NOT NULL column.

### Installation

On Linux systems, *pg\_repack* is provided together with Postgres Pro Enterprise as a separate pre-built package `pg-repack-ent-14` and requires the `postgrespro-ent-14-server` package to be installed with all the dependencies. For the list of available packages and detailed installation instructions, see [Chapter 17](#). On Windows systems, *pg\_repack* is automatically installed as part of Postgres Pro.

Once you have *pg\_repack* installed, load the *pg\_repack* extension in the database you want to process, as follows:

```
$ psql -c "CREATE EXTENSION pg_repack" -d your_database
```

You can later remove *pg\_repack* from a Postgres Pro installation using `DROP EXTENSION pg_repack`.

If you are upgrading from a previous version of *pg\_repack*, just drop the old version from the database as explained above and install the new version.

### Options

#### Reorganization Options

```
-a  
--all
```

Attempt to repack all the databases of the cluster. Databases where the *pg\_repack* extension is not installed will be skipped.

`-t table`  
`--table=table`

Reorganize the specified table(s) only. Multiple tables may be reorganized by writing multiple `-t` switches. By default, all eligible tables in the target databases are reorganized.

`-I table`  
`--parent-table=table`

Reorganize both the specified table(s) and its inheritors. Multiple table hierarchies may be reorganized by writing multiple `-I` switches.

`-c schema`  
`--schema=schema`

Repack the tables in the specified schema(s) only. Multiple schemas may be repacked by writing multiple `-c` switches. Can be used in conjunction with `--tablespace` to move tables to a different tablespace.

`-o column[, ...]`  
`--order-by=column[, ...]`

Perform an online `CLUSTER` ordered by the specified columns.

`-n`  
`--no-order`

Perform an online `VACUUM FULL`. Since version 1.2 this is the default for non-clustered tables.

`-N`  
`--dry-run`

Show what would be repacked and exit.

`-j num_jobs`  
`--jobs=num_jobs`

Create the specified number of extra connections to Postgres Pro, and use these extra connections to parallelize the rebuild of indexes on each table. Parallel index builds are only supported for full-table repacks, not with `--index` or `--only-indexes` options. If your server has extra cores and disk I/O available, this can be a useful way to speed up `pg_repack`.

`-s tablespace`  
`--tablespace=tablespace`

Move the repacked tables to the specified tablespace: essentially an online version of `ALTER TABLE ... SET TABLESPACE`. The tables' indexes are left in the original tablespace unless `--moveidx` is specified too.

`-S`  
`--moveidx`

Also move the indexes of the repacked tables to the tablespace specified by the `--tablespace` option.

`-i index`  
`--index=index`

Repack the specified index(es) only. Multiple indexes may be repacked by writing multiple `-i` switches. May be used in conjunction with `--tablespace` to move the index(es) to a different tablespace.

`-x`  
`--only-indexes`

Repack only the indexes of the specified table(s), which must be specified with the `--table` option.

`-T secs`

`--wait-timeout=secs`

`pg_repack` needs to take an exclusive lock at the end of the reorganization. This setting controls how many seconds `pg_repack` will wait to acquire this lock. If the lock cannot be taken after this duration and `--no-kill-backend` option is not specified, `pg_repack` will forcibly cancel the conflicting queries. If you are using Postgres Pro or PostgreSQL version 8.4 or newer, `pg_repack` will fall back to using `pg_terminate_backend()` to disconnect any remaining backends after this timeout has passed twice. The default is 60 seconds.

`-D`

`--no-kill-backend`

Skip repacking a table if the lock cannot be taken for duration specified in `--wait-timeout`, instead of cancelling conflicting queries. The default is `false`.

`-Z`

`--no-analyze`

Disable `ANALYZE` after a full-table reorganization. If not specified, `ANALYZE` is executed after the reorganization.

`-k`

`--no-superuser-check`

Skip the superuser checks in the client. This setting is useful for using `pg_repack` on platforms that support running it as non-superusers.

`-C`

`--exclude-extension`

Skip tables that belong to the specified extension(s). Some extensions may heavily depend on such tables at planning time etc.

`--switch-threshold`

Switch tables when that many tuples are left in the log table. This setting can be used to avoid the inability to catch up with write-heavy tables.

## Connection Options

Options to connect to servers. You cannot use `--all` and `--dbname` or `--table` or `--parent-table` together.

`-a`

`--all`

Reorganize all databases.

`[-d] dbname`

`[--dbname=] dbname`

Specifies the name of the database to be reorganized. If this is not specified and `-a` (or `--all`) is not used, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used.

`-h host`

`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`

`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

```
-U username
--username=username
```

User name to connect as.

```
-w
--no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W
--password
```

Force `pg_repack` to prompt for a password before connecting to a database.

This option is never essential, since `pg_repack` will automatically prompt for a password if the server demands password authentication. However, `pg_repack` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

## Generic Options

```
-e
--echo
```

Echo the commands that `pg_repack` generates and sends to the server.

```
-E level
--elevel=level
```

Choose the output message level from `DEBUG`, `INFO`, `NOTICE`, `WARNING`, `ERROR`, `LOG`, `FATAL`, and `PANIC`. The default is `INFO`.

```
--help
```

Show help about `pg_repack` command line arguments, and exit.

```
-V
--version
```

Print the `pg_repack` version and exit.

## Environment

```
PGDATABASE
PGHOST
PGPORT
PGUSER
```

Default connection parameters

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by `libpq` (see [Section 36.15](#)).

## Examples

Perform an online `CLUSTER` of all the clustered tables in the database `test`, and perform an online `VACUUM FULL` of all the non-clustered tables:

```
$ pg_repack test
```

Perform an online `VACUUM FULL` on the tables `foo` and `bar` in the database `test` (an eventual cluster index is ignored):

```
$ pg_repack --no-order --table foo --table bar test
```

Move all indexes of table `foo` to tablespace `tbs`:

```
$ pg_repack -d test --table foo --only-indexes --tablespace tbs
```

Move the specified index to tablespace `tbs`:

```
$ pg_repack -d test --index idx --tablespace tbs
```

## Diagnostics

Error messages are reported when `pg_repack` fails. The following list shows the cause of errors.

You need to cleanup by hand after fatal errors. To cleanup, just remove `pg_repack` from the database and install it again.

For Postgres Pro or PostgreSQL 9.1 and newer execute:

```
DROP EXTENSION pg_repack CASCADE
```

in the database where the error occurred, followed by

```
CREATE EXTENSION pg_repack
```

For previous versions load the script `$SHAREDIR/contrib/uninstall_pg_repack.sql` into the database where the error occurred and then load `$SHAREDIR/contrib/pg_repack.sql` again.

```
INFO: database "db" skipped:
```

```
pg_repack VER is not installed in the database:
```

```
pg_repack is not installed in the database when the --all option is specified.
```

Create the `pg_repack` extension in the database.

```
ERROR: pg_repack VER is not installed in the database:
```

```
pg_repack is not installed in the database specified by --dbname
```

Create the `pg_repack` extension in the database.

```
ERROR: program 'pg_repack V1' does not match database library 'pg_repack V2':  
There is a mismatch between the pg_repack binary and the database library  
(.so or .dll).
```

The mismatch could be due to the wrong binary in the `PATH` or the wrong database being addressed. Check the program directory and the database; if they are what expected you may need to repeat `pg_repack` installation.

```
ERROR: extension 'pg_repack V1' required, found 'pg_repack V2':
```

```
The SQL extension found in the database does not match the version required by the  
pg_repack program.
```

You should drop the extension from the database and reload it as described in [the section called “Installation”](#).

```
ERROR: relation "table" must have a primary key or not-null unique keys:
```

The target table doesn't have a PRIMARY KEY or any UNIQUE constraints defined.

Define a PRIMARY KEY or a UNIQUE constraint on the table.

```
ERROR: query failed: ERROR: column "col" does not exist:
The target table doesn't have columns specified by --order-by option.
```

Specify existing columns.

```
WARNING: the table "tbl" already has a trigger called z_repack_trigger:
The trigger was probably installed during a previous attempt
to run pg_repack on the table which was interrupted
and for some reason failed to clean up the temporary objects.
```

You can remove all the temporary objects by dropping and re-creating the extension: see [the section called “Installation”](#) for the details.

```
WARNING: trigger "trg" conflicting on table "tbl":
The target table has a trigger whose name follows z_repack_trigger
in alphabetical order.
```

The `z_repack_trigger` should be the last BEFORE trigger to fire. Please rename your trigger so that it sorts alphabetically before `pg_repack` one; you can use:

```
ALTER TRIGGER zzz_my_trigger
ON sometable RENAME TO yyy_my_trigger;
```

```
ERROR: Another pg_repack command may be running on the table. Please try again later.
```

There is a chance of deadlock when two concurrent `pg_repack` commands are run on the same table. So, try to run the command after some time.

```
WARNING: Cannot create index "schema"."index_xxxxx", already exists
DETAIL: An invalid index may have been left behind by a previous
pg_repack on the table which was interrupted. Please use DROP INDEX
"schema"."index_xxxxx" to remove this index and try again.
```

A temporary index apparently created by `pg_repack` has been left behind, and we do not want to risk dropping this index ourselves. If the index was in fact created by an old `pg_repack` job which didn't get cleaned up, you should just use `DROP INDEX` and try the `repack` command again.

## Restrictions

`pg_repack` comes with the following restrictions.

Temporary tables

`pg_repack` cannot reorganize temporary tables.

GiST indexes

`pg_repack` cannot cluster tables by GiST indexes.

## DDL commands

You will not be able to perform DDL commands of the target table(s) *except* `VACUUM` or `ANALYZE` while `pg_repack` is working. `pg_repack` will hold an `ACCESS SHARE` lock on the target table during a full-table repack, to enforce this restriction.

If you are using version 1.1.8 or earlier, you must not attempt to perform any DDL commands on the target table(s) while `pg_repack` is running. In many cases `pg_repack` would fail and rollback correctly, but there were some cases in these earlier versions which could result in data corruption.

## See also

[clusterdb](#), [vacuumdb](#)

## I.3. Additional Postgres Pro Server Applications

This section covers Postgres Pro Enterprise server-related applications. They are typically run on the host where the database server resides. See also [Postgres Pro Server Applications](#) for information about server applications that are part of the core Postgres Pro Enterprise distribution.

## mamonsu

mamonsu — a monitoring agent for collecting Postgres Pro and system metrics

### Synopsis

```
mamonsu agent [agent_action]  
  
mamonsu bootstrap -M mamonsu_user [-c | --config] [-x | --create-extensions] [connection_options]  
  
mamonsu export {template | config} filename [export_options]  
  
mamonsu report [report_options] [connection_options]  
  
mamonsu tune [tuning_options] [connection_options]  
  
mamonsu upload [upload_options]  
  
mamonsu zabbix dashboard upload template_name  
  
mamonsu zabbix {template | host | hostgroup} server_action  
  
mamonsu zabbix item {error | lastvalue | lastclock} host_id  
  
mamonsu zabbix version  
  
mamonsu [-c | --config] [-d | --daemonize]  
  
mamonsu --version  
  
mamonsu --help
```

### Description

mamonsu is a monitoring agent for collecting Postgres Pro and system metrics that can be visualized on the Zabbix server. Unlike the native Zabbix Agent configured to collect Postgres Pro metrics, mamonsu uses a single database connection, which allows to minimize performance impact on the monitored system.

The mamonsu agent includes the following components:

- A supervisor process that monitors database and system activity.
- Plugins that specify which Postgres Pro and system metrics to collect.
- Customizable configuration and template files that define which plugins to use and how to visualize the collected data.

mamonsu is an active agent, which means that it sends the data to the Zabbix server once it is collected. Pre-configured to monitor multiple Postgres Pro and system metrics out of the box, mamonsu can be extended with your own custom plugins to track other metrics critical for your system.

mamonsu also provides the command-line interface for updating some Zabbix server settings, as well as getting an overview of the monitored system configuration and tuning Postgres Pro and system settings on the fly. You can find the list of all mamonsu commands in [the section called “Command-Line Reference”](#).

### Installation and Setup

#### Important

Before you start installation, attentively read [Compatibility Considerations](#).

To use `mamonsu`, you must create a Zabbix account and set up a Zabbix server as explained in [Zabbix documentation](#). Naturally, you must also have a Postgres Pro instance up and running if you are going to monitor Postgres Pro metrics. If you are configuring your Postgres Pro cluster from scratch, see [Chapter 17](#) and [Section 18.2](#) for Postgres Pro installation and setup instructions, respectively.

### Note

While `mamonsu` can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

`mamonsu` is provided with Postgres Pro Enterprise as a separate pre-built package `mamonsu` (for the detailed installation instructions, see [Chapter 17](#)). Once you have installed `mamonsu`, complete the following steps to set up metrics collection:

#### 1. Optionally, bootstrap `mamonsu`

If you omit this step, metrics can only be collected on behalf of a superuser, which is not recommended.

In this step, the `bootstrap` command sets the `mamonsu` user, creates `mamonsu` schema in the specified or implied database, as well as extensions and objects needed for monitoring.

`bootstrap` has no mandatory options. When run without options, it takes the values needed from the configuration file (`/etc/mamonsu/agent.conf` by default). Below is a simple example of `bootstrap`:

1. In the `[postgres]` section of `agent.conf`, specify connection parameters for the Postgres Pro cluster you are going to monitor. For more details, see [Connection Parameters](#).
2. Run the following command to bootstrap `mamonsu`:

```
mamonsu bootstrap
```

This command will create the user `mamonsu` with the password `mamonsu`, create monitoring functions in the database specified in `agent.conf` and grant the right to execute them to the `mamonsu` user.

In the following example, `bootstrap` options are passed explicitly.

1. Create a non-privileged database user for `mamonsu`. For example:

```
CREATE USER mamonsu_user WITH PASSWORD 'mamonsu_password';
GRANT pg_monitor TO mamonsu_user;
```

2. Create a database that will be used for connection to Postgres Pro. For example:

```
CREATE DATABASE mamonsu_database OWNER mamonsu_user;
```

3. Run the following command to bootstrap `mamonsu`:

```
mamonsu bootstrap -M mamonsu_user -x -c /etc/mamonsu/agent.conf -d
mamonsu_database -U postgres --host myhost --port 5432
```

For details of the options `-M`, `-x` and `-c`, see [bootstrap](#). For details of other options, see [Connection Options](#). This command will create monitoring functions in the `mamonsu_database` and grant the right to execute them to `mamonsu_user`. The `pg_buffercache` extension will also be created to ensure collection of metrics on the shared buffer cache, and the path to the configuration file will be changed.

As a result, a superuser connection is no longer required. Note that `mamonsu` also creates several tables in the `mamonsu` schema in the specified database. Do not delete these tables as they are required for `mamonsu` to work.

## 2. Configure mamonsu

Edit the `agent.conf` configuration file, which is located in the `/etc/mamonsu/` directory by default.

- Configure Zabbix-related settings. The `address` field must point to the running Zabbix server, while the `client` field must provide the name of the Zabbix host. You can find the list of hosts available for your account in the Zabbix web interface under **Configuration > Hosts**.

```
[zabbix]
; enabled by default
enabled = True
client = zabbix_host_name
address = zabbix_server
```

- By default, mamonsu will collect both Postgres Pro and system metrics. If required, you can disable metrics collection of either type by setting the `enabled` parameter to `False` in the `[postgres]` or `[system]` section of the `agent.conf` file, respectively.

```
[system]
; enabled by default
enabled = True
```

### Note

While mamonsu can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

- If you are going to collect Postgres Pro metrics, specify connection parameters for the Postgres Pro cluster you are going to monitor. In the `user`, `password`, and `database` fields, you must specify the `mamonsu_user`, `mamonsu_password`, and the `mamonsu_database` used for bootstrap, respectively. If you skipped the bootstrap, specify superuser credentials and the database to connect to.

```
[postgres]
; enabled by default
enabled = True
user = mamonsu_user
database = mamonsu_database
password = mamonsu_password
port = 5432
```

These are the main mamonsu settings to get started. You can also fine-tune other mamonsu settings as explained in [the section called “Configuration Parameters”](#).

## 3. Configure how to display metrics on the Zabbix server

1. Generate a template that defines how to visualize the collected metrics on the Zabbix server:

```
mamonsu export template template.xml
```

mamonsu generates the `template.xml` file in your current directory. By default, the name of the template that will be displayed in the Zabbix account is `PostgresPro-OS`, where `OS` is the name of your operating system. To get a template with a different display name, you can run the above command with the `--template-name` option.

2. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:

- Set the `ZABBIX_USER` and `ZABBIX_PASSWD` variables to the login and password of your Zabbix account, respectively.
- Set the `ZABBIX_URL` to `http://zabbix/`

If you skip this step, you will have to add the following options to all `mamonsu zabbix` commands that you run:

```
--url=http://zabbix/ --user=zabbix_login --password=zabbix_password
```

3. Upload `template.xml` to the Zabbix server.

```
mamonsu zabbix template export template.xml
```

Alternatively, you can upload the template through the Zabbix web interface: log in to your Zabbix account and select **Templates > Import**.

4. Link the generated template to the host to be monitored.

In the Zabbix web interface, select your host, go to **Templates > Add**, select your template, and click **Update**.

### Tip

If you would like to link a template with a new Zabbix host, you can do it from the command line using `mamonsu zabbix` commands. See [the section called “Managing Zabbix Server Settings from the Command Line”](#) for details.

When the setup is complete, start `mamonsu`. For example, on Linux systems, you can start `mamonsu` as a service with the following command:

```
service mamonsu start
```

`mamonsu` picks up all the parameters from the `mamonsu` configuration file and starts monitoring your system.

## Command-Line Reference

### agent

Syntax:

```
mamonsu agent { metric-list | metric-get metric_name | version }
```

Provide information on the collected metrics from the command line. You can specify one of the following parameters:

`metric-list`

Show the list of metrics that `mamonsu` is collecting. The output of this command provides the item key of each metric, its latest value, and the time when this value was received.

`metric-get metric_name`

Check the latest value for the specified metric. You can get the list of available metrics using the `metric-list` option.

`version`

Display `mamonsu` version.

### bootstrap

Syntax:

```
mamonsu bootstrap -M mamonsu_user
    [-c[ config_file] | --config[=config_file]]
    [-x | --create-extensions] [connection_options]
```

Bootstrap mamonsu. This command can take the following options:

**-M**  
Specify a non-privileged user that will own all mamonsu processes.

**-c *config\_file***  
**--config=*config\_file***  
Specify the `agent.conf` file where the `[postgres]` section contains the database name to be used if `--dbname` is not specified through *connection\_options*.  
  
Default: `/etc/mamonsu/agent.conf`

**-x**  
**--create-extensions**  
Create auxiliary extensions. The `pg_buffercache` extension will be created, which is no longer created by default. For Postgres Pro 12 or higher, the `bootstrap -x` command will also create functions to work with the `pgpro_stats` extension and grant the right to execute them to the `mamonsu` user.

***connection\_options***  
Provide optional *command-line connection parameters*.

## export

Syntax:

```
mamonsu export config filename.conf [--add-plugins=plugin_directory]
mamonsu export template filename.xml [--add-plugins=plugin_directory]
                                     [--template-name=template_name]
                                     [--application=application_name]
                                     [--old-zabbix]
```

Generate a template or configuration file for metrics collection. The optional parameters to customize metrics collection are as follows:

**--add-plugins=*plugin\_directory***  
Collect metrics that are defined in custom plugins located in the specified *plugin\_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

**--template-name=*template\_name***  
Specify the name of the template that will be displayed on the Zabbix server.  
  
Default: `PostgresPro-OS`, where *OS* is the name of your operating system

**--application=*application\_name***  
Specify an identifier under which the collected metrics will be displayed on the Zabbix server.  
  
Default: `App-PostgresPro-OS`, where *OS* is the name of your operating system

**--old-zabbix**  
Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

**export zabbix-parameters**

Syntax:

```
mamonsu export zabbix-parameters filename.conf [--add-plugins=plugin_directory]
                                           [--plugin-type={pg | sys | all}]
                                           [--pg-version=version]
                                           [--config=config_file]
```

Export metrics configuration for use with the native [Zabbix agent](#). The optional parameters to customize metrics collection are as follows:

`--add-plugins=plugin_directory`

Collect metrics that are defined in custom plugins located in the specified *plugin\_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

`--plugin-type={pg | sys | all}`

Specify the type of metrics to collect:

- `pg` for Postgres Pro metrics.
- `sys` for system metrics.
- `all` for both Postgres Pro and system metrics.

Default: `all`

`--pg-version=version`

Specify the major version of the server for which to configure metrics collection. `mamonsu` can collect metrics for all supported Postgres Pro versions, as well as PostgreSQL versions starting from 9.5.

Default: `10`

`--config=config_file`

Specify the `agent.conf` file to be used as the source for metrics definitions.

Default: `/etc/mamonsu/agent.conf`

**export zabbix-template**

Syntax:

```
mamonsu export zabbix-template filename.conf [--add-plugins=plugin_directory]
                                           [--plugin-type={pg | sys | all}]
                                           [--template-name=template_name]
                                           [--application=application_name]
                                           [--config=config_file]
                                           [--old-zabbix]
```

Export a template for use with the native Zabbix agent. The optional parameters to customize metrics collection are as follows:

`--add-plugins=plugin_directory`

Collect metrics that are defined in custom plugins located in the specified *plugin\_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

`--plugin-type={pg | sys | all}`

Specify the type of metrics to collect:

- `pg` configures Postgres Pro metrics.
- `sys` configures system metrics.
- `all` configures both Postgres Pro and system metrics.

Default: `all`

`--template-name=template_name`

Specify the name of the template that will be displayed on the Zabbix server.

Default: `PostgresPro-OS`, where *OS* is the name of your operating system

`--application=application_name`

Specify an identifier under which the collected metrics will be displayed on the Zabbix server.

Default: `App-PostgresPro-OS`, where *OS* is the name of your operating system

`--config=config_file`

Specify the `agent.conf` file to be used as the source for metrics definitions.

Default: `/etc/mamonsu/agent.conf`

`--old-zabbix`

Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

## report

Syntax:

```
mamonsu report [--run-system=Boolean] [--run-postgres=Boolean]
               [--print-report=Boolean] [--report-path=report_file]
               [--disable-sudo] [connection_options]
```

Generate a detailed report on the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration.

The following optional parameters customize the report:

`--run-system=Boolean`

Include system information into the generated report.

Default: `True`

`--run-postgres=Boolean`

Include information on Postgres Pro into the generated report.

Default: `True`

`--print-report=Boolean`

Print the report to stdout.

Default: `True`

`--report-path=report_file`

Save the report into the specified file.

Default: `/tmp/report.txt`

`--disable-sudo`

Do not report data that can only be received with superuser rights. This option is only available for Linux systems.

*connection\_options*

Provide optional *command-line connection parameters*.

## tune

Syntax:

```
mamonsu tune [--dry-run] [--disable-sudo] [--log-level {INFO|DEBUG|WARN}]
             [--dont-tune-pgbadger] [--dont-reload-postgresql]
             [connection_options]
```

Optimize Postgres Pro and system configuration based on the collected statistics. You can use the following options:

`--dry-run`

Display the settings to be tuned without changing the actual system and Postgres Pro configuration.

`--disable-sudo`

Do not tune the settings that can only be changed by a superuser. This option is only available for Linux systems.

`--dont-tune-pgbadger`

Do not tune *pgbadger* parameters.

`--log-level { INFO | DEBUG | WARN }`

Change the logging level.

Default: INFO

`--dont-reload-postgresql`

Forbid mamonsu to run the `pg_reload_conf()` function. If you specify this option, the modified settings that require reloading Postgres Pro configuration do not take effect immediately.

*connection\_options*

Provide optional *command-line connection parameters*.

## upload

Syntax:

```
mamonsu upload [--zabbix-file=metrics_file]
               [--zabbix-address=zabbix_address] [--zabbix-port=port_number]
               [--zabbix-client=zabbix_host_name] [--zabbix-log-level={INFO|DEBUG|
WARN}]
```

Upload metrics data previously saved into a file onto a Zabbix server for visualization. For details on how to save metrics into a file, see [the section called “Logging Parameters”](#).

This command can take the following options:

`--zabbix-address=zabbix_address`

The address of the Zabbix server.

Default: localhost

`--zabbix-port=port_number`

The port of the Zabbix server.

Default: 10051

`--zabbix-file=metrics_file`

A text file that stores the collected metrics data to be visualized, such as `localhost.log`.

`--zabbix-client=zabbix_host_name`

The name of the Zabbix host.

Default: `localhost`

`--zabbix-log-level={INFO|DEBUG|WARN}`

Change the logging level.

Default: `INFO`

### **zabbix dashboard upload**

Syntax:

`mamonsu dashboard upload template_name`

Upload a Zabbix dashboard with the mamonsu metrics to a template on the Zabbix server version 6.0 or higher.

### **zabbix item**

Syntax:

`mamonsu zabbix item {error | lastvalue | lastclock } host_name`

View the specified property of the latest metrics data received by Zabbix for the specified host.

### **zabbix version**

Syntax:

`mamonsu zabbix version`

Get the version of the Zabbix server that mamonsu is connected to.

### **zabbix host**

Syntax:

`mamonsu zabbix host list`

`mamonsu zabbix host show host_name`

`mamonsu zabbix host id host_name`

`mamonsu zabbix host delete host_id`

`mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address`

`mamonsu zabbix host info {templates | hostgroups | graphs | items} host_id`

Manage Zabbix hosts using one of the actions described in [the section called “Zabbix Server Actions”](#).

### **zabbix hostgroup**

Syntax:

`mamonsu zabbix hostgroup list`

`mamonsu zabbix hostgroup show hostgroup_name`

`mamonsu zabbix hostgroup id hostgroup_name`

```
mamonsu zabbix hostgroup delete hostgroup_id
mamonsu zabbix hostgroup create hostgroup_name
```

Manage Zabbix host groups using one of the actions described in [the section called “Zabbix Server Actions”](#).

### **zabbix template**

Syntax:

```
mamonsu zabbix template list
mamonsu zabbix template show template_name
mamonsu zabbix template id template_name
mamonsu zabbix template delete template_id
mamonsu zabbix template export file
```

Manage Zabbix templates using one of the actions described in [the section called “Zabbix Server Actions”](#).

### **[--config] [--daemonize]**

Syntax:

```
mamonsu [-c config_file | --config=config_file]
        [-d | --daemonize]
```

Start working as a monitoring agent in the foreground or in the background using configuration parameters loaded from the configuration file. If the specified or default configuration file does not exist, exit with an error. Useful for debugging. You can specify the following options:

```
-c config_file
--config=config_file
```

Specify the `agent.conf` file where to load the configuration parameters from.

Default: `/etc/mamonsu/agent.conf`

```
-d
--daemonize
```

Run in the background. Without it, mamonsu will run in the foreground.

### **--version**

Syntax:

```
mamonsu --version
```

Display mamonsu version.

### **--help**

Syntax:

```
mamonsu --help
```

Display mamonsu command-line help.

### **Connection Options**

*connection\_options* provide command-line connection parameters for the target Postgres Pro cluster. *connection\_options* can be `--host`, `--port`, `--dbname (-d)`, `--username (-U)`, and `--password (-W)`. The `--dbname` option should specify the *mamonsu\_database* created for monitoring purposes. Note that the `--username (-U)` option must specify a superuser that can access the cluster.

If you omit *connection\_options*, mamonsu checks the configuration file for the needed settings.

## Zabbix Server Actions

Using `mamonsu`, you can control some of the Zabbix server functionality from the command line. Specifically, you can create or delete Zabbix hosts and host groups, as well as generate, import, and delete Zabbix templates using one of the following commands. The *object\_name* to use must correspond to the type of the Zabbix object specified in the command: `template`, `host`, or `hostgroup`.

`list`

Display the list of available templates, hosts, or host groups.

`show object_name`

Display the details about the specified template, host, or host group.

`id object_name`

Show the ID of the specified object, which is assigned automatically by the Zabbix server.

`delete object_id`

Delete the object with the specified ID.

`create hostgroup_name`

`create host_name hostgroup_id template_id mamonsu_address`

Create a new host or a host group.

`export template_name`

Generate a Zabbix template.

`info {templates | hostgroups | graphs | items} host_id`

Display detailed information about the templates, host groups, graphs, and metrics available on the host with the specified ID.

## Configuration Parameters

The `agent.conf` configuration file is located in the `/etc/mamonsu` directory by default. It provides several groups of parameters that control which metrics to collect and how to log the collected data:

- [connection parameters](#)
- [logging parameters](#)
- [plugin parameters](#)

All parameters must be specified in the `parameter = value` format.

### Connection Parameters

#### [postgres]

The `[postgres]` section controls Postgres Pro metrics collection and can contain the following parameters:

`enabled`

Enables/disables Postgres Pro metrics collection if set to `True` or `False`, respectively.

Default: `True`

`user`

The user on behalf of which the cluster will be monitored. It must be the `mamonsu` user set in `bootstrap`, or a superuser if `bootstrap` was not run.

Default: postgres

password

The password for the specified user.

database

The database to connect to for metrics collection.

Default: postgres

host

The server address to connect to.

Default: localhost

port

The port to connect to.

Default: 5432

application\_name

Application name that identifies mamonsu connected to the Postgres Pro cluster.

Default: mamonsu

query\_timeout

[statement\\_timeout](#) for the mamonsu session, in seconds. If a Postgres Pro metric query does not complete within this time interval, it gets terminated.

Default: 10

Alternatively you can specify environment variables rather than the configuration parameters. The following environment variables can be used: PGUSER, PGPASSWORD, PGHOST, PGDATABASE, PGPORT, and PGAPPNAME. See [Section 36.15](#) for their meaning.

#### **[system]**

The [system] section controls system metrics collection and can contain the following parameters:

enabled

Enables/disables system metrics collection if set to True or False, respectively.

Default: True

#### **[zabbix]**

The [zabbix] section provides connection settings for the Zabbix server and can contain the following parameters:

enabled

Enables/disables sending the collected metrics data to the Zabbix server if set to True or False, respectively.

Default: True

client

The name of the Zabbix host.

`address`

The address of the Zabbix server.

Default: 127.0.0.1

`port`

The port of the Zabbix server.

Default: 10051

`timeout`

Maximum time to wait while connecting to the Zabbix server, in seconds.

Default: 15

**[agent]**

The `[agent]` section specifies the location of `mamonsu` and whether it is allowed to access metrics from the command line:

`enabled`

Enables/disables metrics collection from the command line using the `agent` command.

Default: `True`

`host`

The address of the system on which `mamonsu` is running.

Default: 127.0.0.1

`port`

The port on which `mamonsu` is running.

Default: 10052

**[sender]**

The `[sender]` section controls the queue size of the data to be sent to the Zabbix server:

`queue`

The maximum number of collected metric values that can be accumulated locally before `mamonsu` sends them to the Zabbix server. Once the accumulated data is sent, the queue is cleared.

Default: 2048

**Logging Parameters**

**[metric\_log]**

The `[metric_log]` section enables storing the collected metrics data in text files locally. This section can contain the following parameters:

`enabled`

Enables/disables storing the collected metrics data in a text file. If this option is set to `True`, `mamonsu` creates the `localhost.log` file for storing metric values.

Default: `False`

`directory`

Specifies the directory where log files with metrics data will be stored.

Default: `/var/log/mamonsu`

`max_size_mb`

The maximum size of a log file, in MB. When the specified size is reached, it is renamed to `localhost.log.archive`, and an empty `localhost.log` file is created.

Default: 1024

### [log]

The `[log]` section specifies logging settings for mamonsu and can contain the following parameters:

`file`

Specifies the log filename, which can be preceded by the full path.

`level`

Specifies the debug level. This option can take `DEBUG`, `ERROR`, or `INFO` values.

Default: `INFO`

`format`

The format of the logged data.

Default: `[% (levelname)s] %(asctime)s - %(name)s - %(message)s`

where `levelname` is the debug level, `asctime` returns the current time, `name` specifies the plugin that emitted this log entry or `root` otherwise, and `message` provides the actual log message.

## Plugin Parameters

### [plugins]

The `[plugins]` section specifies custom plugins to be added for metrics collection and can contain the following parameters:

`enabled`

Enables/disables using custom plugins for metrics collection if set to `True` or `False`, respectively.

Default: `False`

`directory`

Specifies the directory that contains custom plugins for metrics collection. Setting this parameter to `None` forbids using custom plugins.

Default: `/etc/mamonsu/plugins`

If you need to configure any of the plugins you add to mamonsu after installation, you have to add this plugin section to the `agent.conf` file.

The syntax of this section should follow the syntax used with the examples shown below in [the section called “Individual Plugin Sections”](#).

## Individual Plugin Sections

All built-in plugins are installed along with mamonsu. To configure a built-in plugin you should find a corresponding section below the Individual Plugin Sections heading and edit its parameter values:

`enabled`

Enables/disables using built-in plugins if set to `True` or `False`, respectively. These values are case-sensitive.

Default: False

interval

Specifies the plugin operation interval, in seconds. The parameter is set with an integer specifying the plugin operation interval in seconds. You can set different intervals for different plugins. For plugins that collect PostgreSQL/ Postgres Pro metrics, for example, autovacuum, checkpoint, etc., this is the interval within which mamonsu accesses the Postgres Pro instance for metrics collection. For system plugins, for example, diskstats, memory, etc., this is the interval within which the operating system is accessed. For service plugins, for example, agentapi, logsender, zbxsender, this is the interval within which their functions are called. Note that the `interval` parameter of the `zbxsender` plugin is associated with the `timeout` parameter of the `[zabbix]` section. The maximum Zabbix server response timeout greater than the plugin operation interval may cause misbehavior of the `zbxsender` plugin: the plugin restarts with an error message if the connection or data transfer require longer time than the value specified in the `interval` parameter.

Default: 60

The example below shows individual plugin sections corresponding to the `preparedtransaction` and the `pgprobackup` built-in plugins:

```
[preparedtransaction]
max_prepared_transaction_time = 60
interval = 60

[pgprobackup]
enabled = false
interval = 300
backup_dirs = /backup_dir1,/backup_dir2
pg_probackup_path = /usr/bin/pg_probackup-11
```

#### [preparedtransaction]

This plugin gets age in seconds of the oldest prepared transaction and number of all transactions prepared for a two-phase commit. For additional information refer to [PREPARE TRANSACTION](#) and [Section 54.81](#).

The `max_prepared_transaction_time` parameter specifies the threshold in seconds for the age of the prepared transaction.

The plugin collects two metrics: `pgsql.prepared.count` (number of prepared transactions) and `pgsql.prepared.oldest` (oldest prepared transaction age in seconds).

If `pgsql.prepared.oldest` value exceeds the threshold specified by the `max_prepared_transaction_time` parameter, a trigger with the following message is fired: "PostgreSQL prepared transaction is too old on {host}".

#### [pgprobackup]

This plugin uses [pg\\_probackup](#) to track its backups' state and gets size of backup directories which store all backup files.

Please note that this plugin counts the total size of all files in the target directory. Make sure that extraneous files are not stored in this directory.

The `backup_dirs` parameter specifies a comma-separated list of paths to directories for which metrics should be collected.

The `pg_probackup_path` parameter specifies the path to `pg_probackup`.

By default this plugin is disabled. To enable it set the `enabled` parameter to `True`.

This plugin collects two metrics: `pg_probackup.dir.size[#backup_directory]` (the size of the target directory) and `pg_probackup.dir.error[#backup_directory]` (backup errors) for each specified `back-up_directory`.

If any generated backup has bad status, like `ERROR`, `CORRUPT`, `ORPHAN`, a trigger is fired.

## Usage

### Collecting and Viewing Metrics Data

Once started, `mamonsu` begins collecting system and Postgres Pro metrics. The `agent` command enables you to get an overview of the collected metrics from the command line in real time.

To view the list of available metrics, use the `agent metric-list` command:

```
mamonsu agent metric-list
```

The output of this command provides the item key of each metric, its latest value, and the time when this value was received. For example:

```
system.memory[active]          7921004544      1564570818
system.memory[swap_cache]      868352      1564570818
pgsql.connections[idle]        6.0        1564570818
pgsql.archive_command[failed_trying_to_archive] 0      1564570818
```

To view the current value for a specific metric, you can use the `agent metric-get` command:

```
mamonsu agent metric-get metric_name
```

where `metric_name` is the item key of the metric to monitor, as returned by the `metric-list` command. For example, `pgsql.connections[idle]`.

You can view graphs for the collected metrics in the Zabbix web interface under the **Graphs** menu. For details on working with Zabbix, see its official documentation at <https://www.zabbix.com/documentation/current/manual>.

If you have chosen to save all the collected metrics data into a file, as explained in [the section called “Logging Parameters”](#), you can later upload these metrics onto a Zabbix server for visualization using the `upload` command.

### Adding Custom Plugins

You can extend `mamonsu` with your own custom plugins, as follows:

1. Save all custom plugins in a single directory, such as `/etc/mamonsu/plugins`.
2. Make sure this directory is specified in your configuration file under the `[plugins]` section:

```
[plugins]
directory = /etc/mamonsu/plugins
```

3. Generate a new Zabbix template to include custom plugins:

```
mamonsu export template template.xml --add-plugins=/etc/mamonsu/plugins
```

4. Upload the generated `template.xml` to the Zabbix server as explained in [the section called “Installation and Setup”](#).

### Tuning Postgres Pro and System Configuration

Based on the collected metrics data, `mamonsu` can tune your Postgres Pro and system configuration for optimal performance.

You can get detailed information about the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration, as follows:

```
mamonsu report
```

To view the suggested optimizations without applying them, run the `tune` command with the `--dry-run` option:

```
mamonsu tune --dry-run
```

To apply all the suggested changes, run the `tune` command without any parameters:

```
mamonsu tune
```

You can exclude some settings from the report or disable some of the optimizations by passing optional parameters. See [the section called “Command-Line Reference”](#) for the full list of parameters available for `report` and `tune` commands.

## Managing Zabbix Server Settings from the Command Line

`mamonsu` enables you to work with the Zabbix server from the command line. You can upload template files to Zabbix, create and delete Zabbix hosts and host groups, link templates with hosts and check the latest metric values.

To set up your Zabbix host from scratch, you can follow these steps:

1. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:
  - Set the `ZABBIX_USER` and `ZABBIX_PASSWD` variables to the login and password of your Zabbix account, respectively.
  - Set the `ZABBIX_URL` to `http://zabbix/`

If you skip this step, you will have to add the following options to all `mamonsu zabbix` commands that you run:

```
--url=http://zabbix/ --user=zabbix_login --password=zabbix_password
```

2. Generate a new template file and upload it to the Zabbix server:

```
mamonsu export template template.xml
mamonsu zabbix template export template.xml
```

3. Create a new host group:

```
mamonsu zabbix hostgroup create hostgroup_name
```

4. Check the IDs for this host group and the uploaded template, which are assigned automatically by the Zabbix server:

```
mamonsu zabbix hostgroup id hostgroup_name
mamonsu zabbix template id template_name
```

5. Create a host associated with this group and link it with the uploaded template using a single command:

```
mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address
```

where *host\_name* is the name of the host, *hostgroup\_id* and *template\_id* are the unique IDs returned in the previous step, and *mamonsu\_address* is the IP address of the system on which `mamonsu` runs.

Once your Zabbix host is configured, complete the setup of your monitoring system as explained in [the section called “Installation and Setup”](#).

## Exporting Metrics for Native Zabbix Agent

Using `mamonsu`, you can convert system and Postgres Pro metrics definitions to the format supported by the native [Zabbix agent](#).

This feature currently has the following limitations:

- You cannot export metrics if you run `mamonsu` on Windows systems.
- Metrics definitions for `pg_wait_sampling` and CFS features available in Postgres Pro Enterprise are not converted.

### Important

To work with Zabbix proxy, you must export settings to the format supported by the native Zabbix agent.

To collect metrics provided by `mamonsu` using the native Zabbix agent, do the following:

1. Generate a configuration file that is compatible with the native Zabbix agent and place it under `/etc/zabbix/zabbix_agent.d/`. You can prepend the filename with the required path:  

```
mamonsu export zabbix-parameters /etc/zabbix/zabbix_agent.d/zabbix_agent.conf
```

For all possible options of the `export zabbix-parameters` command, see [the section called “Command-Line Reference”](#).
2. Generate a template for the native Zabbix agent:  

```
mamonsu export zabbix-template template.xml
```

For all possible options of the `export zabbix-template` command, see [the section called “Command-Line Reference”](#).
3. Upload the generated template to the Zabbix server, as explained in [the section called “Installation and Setup”](#).
4. If you are going to collect Postgres Pro metrics, change the following macros in the template after the upload:
  - For `{$PG_CONNINFO}`, provide connection parameters for the Postgres Pro server to be monitored.
  - For `{$PG_PATH}`, specify `psql` installation directory.

## Compatibility Considerations

If you want to upgrade `mamonsu` to a version that is not compatible with the previous one, what you must do to continue using the application depends on whether you need to retain the metrics data collected.

- If you need to retain the collected data, do the following:
  1. Install the new version of `mamonsu`.
  2. Generate a new template for the Zabbix server.
  3. If you performed a bootstrap using the previous version of `mamonsu`, run the `bootstrap` command again.
  4. Upload the new template to the Zabbix server.
  5. Rename the host for which you want to retain the collected data and leave the old template linked to that host.
  6. Create a new host for the same system and link the new template to it.
  7. Restart `mamonsu`. It will collect data for the new host. The old host will no longer be used, but the data collected will be available.
- If you do not need to retain the collected data, do the following:
  1. Install the new version of `mamonsu`.
  2. Generate a new template for the Zabbix server.

3. If you performed a bootstrap using the previous version of mamonsu, run the `bootstrap` command again.
4. Upload the new template to the Zabbix server.
5. In the settings of the Zabbix host, link the new template to the host instead of the old one.
6. Restart mamonsu. It will start collecting data. All the data collected earlier will be lost.

## pgpro\_controldata

`pgpro_controldata` — display control information of a PostgreSQL/Postgres Pro database cluster and compatibility information for a cluster and/or server

## Synopsis

```
pgpro_controldata [option...]
```

## Description

`pgpro_controldata` prints control information, such as the catalog version, initialized by `initdb` command of any PostgreSQL/Postgres Pro server. It also shows information about write-ahead logging and checkpoint processing. This information is cluster-wide and not specific to any database.

`pgpro_controldata` also helps to check compatibility between PostgreSQL/Postgres Pro database servers and clusters. It can print server or cluster parameters that can affect the compatibility and check whether a cluster and server are compatible by comparing those parameters.

`pgpro_controldata` is provided with Postgres Pro Enterprise as a separate pre-built package `pgpro-controldata` (for the detailed installation instructions, see [Chapter 17](#)).

## Options

`pgpro_controldata` accepts the following command-line arguments. If no arguments are specified, `pgpro_controldata` just prints the control information like [pg\\_controldata](#) does. Note that compatibility-related command-line arguments `-P` and `-S` specified together work the same way as `-C`.

### General-Purpose

`-B`  
`--bindir`  
Specifies the PostgreSQL/Postgres Pro executable directory, needed to get server compatibility parameters.

`-D datadir`  
`--pgdata=datadir`  
Specifies the file system location of the database configuration files. If this option is omitted, the environment variable `PGDATA` is used.

`-V`  
`--version`  
Print the `pgpro_controldata` version, then exit.

`-?`  
`--help`  
Show help about `pgpro_controldata` command-line arguments, then exit.

### Compatibility-Related

`-C`  
`--compatibility-check`  
Display all parameters that can affect compatibility between the specified server and cluster and check whether they are compatible.

Use the `-D` option or the environment variable `PGDATA` to provide the path to the data directory, where read access is required.

If the `-B` option is omitted, the current server is assumed.

The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

`-P`

`--cluster-compatibility-params`

Display all parameters of the specified cluster that can affect the compatibility.

Use the `-D` option or the environment variable `PGDATA` to provide the path to the data directory, where read access is required.

The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

`-S`

`--server-compatibility-params`

Display all parameters of the specified or current server that can affect the compatibility.

If the `-B` option is omitted, the current server is assumed.

## Environment

`PGDATA`

Default data directory location

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## See Also

[pg\\_controldata](#)

## pg\_integrity\_check

`pg_integrity_check` — calculate and validate checksums for controlled files (certified edition only)

### Synopsis

```
pg_integrity_check [connection-option...] [-s | --system] [-u | --user] [-c | --catalog] [-o | --output]
[-l filename | --log=filename] [--syslog] [-D datadir] [-C filename] [-v | --verbose] [-? | --help]
```

### Description

`pg_integrity_check` is a utility provided with Postgres Pro Enterprise that can calculate and validate checksums for the objects you would like to control. When running `pg_integrity_check`, you must specify at least one of the options that define the type of the controlled objects: `-s`, `-u`, or `-c` for read-only files, additional files, or system catalog tables, respectively.

If you use the `-o` option, `pg_integrity_check` calculates checksums and writes them into configuration files under the `share/security/` directory. You must have write access to the corresponding files to perform this command. You cannot use the `-o` option together with the `-s` option, since a checksum for read-only files cannot be overwritten.

If you omit the `-o` option, `pg_integrity_check` compares the calculated checksums with the corresponding checksums in the configuration files. If the checksums differ for any of the controlled objects, `pg_integrity_check` displays a message indicating the difference.

For details on using `pg_integrity_check`, see [Section 32.2](#).

### Options

*connection-options*

Standard options for connecting to a database: `-d`, `-h`, `-p`, `-U`. You must specify `-d` and `-U` options when validating checksums for catalog tables with the `-c` option. For detailed description of connection options, see [psql](#).

`-s`  
`--system`

Validate checksums for read-only files. Checksums for read-only files control both file contents and file attributes.

`-u`  
`--user`

Validate checksums for additional files. Checksums for additional files control both file contents and file attributes.

`-c`  
`--catalog`

Validate checksums for system catalog tables. For the `-c` option to work correctly, you must also specify connection parameters for the database. The database server must be started and accept connections.

`-o`  
`--output`

Recalculate checksums and write it into a file.

`-l filename`  
`--log=filename`

Write checksum validation results into a log file.

`--syslog`

Write checksum validation results into the syslog.

`-D datadir`

Data directory of the database cluster. This option is required to define the filenames for the generated configuration files when using `-u` option.

`-C filename`

The absolute path to the configuration file used for integrity checks of system catalog tables of the selected database. If used with the `-o` option, `pg_integrity_check` writes into the specified file. If no other option is used, `pg_integrity_check` checks data against the specified file.

`-v`

`--verbose`

Print debugging information, including checksum values.

`-?`

`--help`

Print command-line help.

## Return Values

0 — checksums are calculated or validated successfully.

1 — an error occurred during the initial checksum calculation for read-only files.

2 — checksum validation revealed changes in one or more of the controlled objects.

3 — an unexpected error occurred during checksum validation.

## Examples

Compute checksums for additional files and write them into the `share/security/_var_lib_pgpro_ent-14_data.user.conf` configuration file:

```
pg_integrity_check -u -o -D /var/lib/pgpro/ent-14/data
```

Check integrity of all controlled objects in the `postgres` database on behalf of the `postgres` user:

```
pg_integrity_check -s -u -c -D /var/lib/pgpro/ent-14/data -d postgres -h localhost -p  
5432 -U postgres
```

## I.4. Third-Party Server Applications

This section covers third-party server-related applications. They are typically run on the host where the database server resides.

## pgbouncer

pgbouncer — a connection pooler for Postgres Pro

### Synopsis

On Linux systems:

```
pgbouncer [ -d ] [ -R ] [ -v ] [ -u user ] pgbouncer.ini
```

```
pgbouncer -V | -h
```

On Windows:

```
pgbouncer [ -v ] [ -u user ] pgbouncer.ini
```

```
pgbouncer -V | -h
```

To use pgbouncer as a Windows service:

```
pgbouncer.exe --regservice pgbouncer.ini
```

```
pgbouncer.exe --unregservice pgbouncer.ini
```

### Description

pgbouncer is a connection pooler for Postgres Pro. Any target application can be connected to pgbouncer as if it were a Postgres Pro server, and pgbouncer will create a connection to the actual server, or it will reuse one of its existing connections.

The aim of pgbouncer is to lower the performance impact of opening new connections to Postgres Pro.

In order not to compromise transaction semantics for connection pooling, pgbouncer supports several types of pooling when rotating connections:

#### Session pooling

Most polite method. When a client connects, a server connection will be assigned to it for the whole duration the client stays connected. When the client disconnects, the server connection will be put back into the pool. This is the default method.

#### Transaction pooling

A server connection is assigned to a client only during a transaction. When pgbouncer notices that transaction is over, the server connection will be put back into the pool.

#### Statement pooling

Most aggressive method. The server connection will be put back into the pool immediately after a query completes. Multi-statement transactions are disallowed in this mode as they would break.

The administration interface of pgbouncer consists of some new `SHOW` commands available when connected to a special “virtual” database `pgbouncer`.

### Quick Start

pgbouncer is provided with Postgres Pro Enterprise as a separate pre-built package `pgbouncer` (for the detailed installation instructions, see [Chapter 17](#)). Basic setup and usage is as follows.

1. Create a `pgbouncer.ini` file. Details in the `pgbouncer(5)` man page. Simple example:

```
[databases]
template1 = host=localhost dbname=template1 auth_user=someuser
```

```
[pgbouncer]
listen_port = 6432
listen_addr = localhost
auth_type = md5
auth_file = userlist.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
```

2. Create a `userlist.txt` file that contains the users allowed in:

```
"someuser" "same_password_as_in_server"
```

3. Launch pgbouncer:

```
$ pgbouncer -d pgbouncer.ini
```

### Note

The above command does not work on Windows systems. Instead, pgbouncer must be launched as a service that first needs to be registered, as follows:

```
pgbouncer --regservice
```

4. Have your application (or the `psql` client) connect to pgbouncer instead of directly to the PostgreSQL server:

```
$ psql -p 6432 -U someuser template1
```

5. Manage pgbouncer by connecting to the special administration database pgbouncer and issuing `SHOW HELP`; to begin:

```
$ psql -p 6432 -U someuser pgbouncer
pgbouncer=# SHOW HELP;
NOTICE:  Console usage
DETAIL:
SHOW [HELP|CONFIG|DATABASES|FDS|POOLS|CLIENTS|SERVERS|SOCKETS|LISTS|VERSION|...]
SET key = arg
RELOAD
PAUSE
SUSPEND
RESUME
SHUTDOWN
[...]
```

6. If you made changes to the `pgbouncer.ini` file, you can reload it with:

```
pgbouncer=# RELOAD;
```

## LDAP Authentication Configuration

pgbouncer supports LDAP authentication for DBMS users. You can configure LDAP authentication by means of [PAM \(Pluggable Authentication Modules\)](#).

This section contains an example of LDAP authentication configuration.

To enable LDAP authentication via pgbouncer, perform the following steps:

- Ensure you fulfill all the required [prerequisites](#).
- [Configure Postgres Pro](#).  
[Configure pgbouncer](#).
- [Configure PAM](#).
- [Test LDAP authentication](#).

### Prerequisites

Before you start LDAP configuration, ensure that you have all required packages installed. If required, install any missing packages.

1. To ensure that your pgbouncer installation includes the PAM library (libpam), use the ldd utility:

```
$ ldd /usr/sbin/pgbouncer | grep pam
libpam.so.0 => /lib64/libpam.so.0 (0x00007fb5d6dd7000)
```

2. Ensure that your system includes the pam\_ldap module:

```
$ find / -type f -name pam_ldap.so 2>/dev/null
/usr/lib64/security/pam_ldap.so
```

3. (Optional) If necessary, install pam\_ldap:

```
apt-get install pam_ldap
```

### Configuring Postgres Pro

1. In your Postgres Pro Enterprise instance, create a test user for LDAP authentication:

```
CREATE USER testuser WITH PASSWORD 'testuser_password';
```

2. In the pg\_hba.conf file, specify the connection string for testuser. For example:

```
host      all      testuser      0.0.0.0/0      ldap
ldapurl=ldap_server_uri
ldapbasedn="CN=testuser,CN=Users,DC=postgrespro,DC=ru"
ldapbinddn="CN=service_user,CN=Users,DC=postgrespro,DC=ru"
ldapbindpasswd="service_user_password"
ldapsearchattribute=CN
```

For more information about LDAP authentication configuration options, see [Section 20.10](#).

As a result, the authentication operates as follows:

1. A user connects to Postgres Pro as testuser.
2. Postgres Pro connects to the LDAP server at ldapurl using ldapbinddn and ldapbindpasswd.
3. In ldapbasedn, Postgres Pro searches for an object where ldapsearchattribute is testuser.
4. Postgres Pro verifies the testuser password via LDAP.

### Note

In a production environment, it is recommended to specify a container or an OU (OrganizationUnitName) as the ldapbasedn value (for example, CN=Users,DC=postgrespro,DC=ru), so that the user name is not hardcoded, but searched via ldapsearchattribute.

### Configuring pgbouncer

1. In the [pgbouncer.ini](#) configuration file, specify the auth\_type = pam authentication method.

The example of pgbouncer configuration looks as follows:

```
[pgbouncer]
listen_addr = *
listen_port = 6500
unix_socket_dir = /tmp/
pool_mode = session
max_client_conn = 15000
default_pool_size = 5
peer_id = 1
so_reuseport = 1
auth_type = pam
admin_users=pgbouncer,testuser
stats_users=pgbouncer,testuser
```

```
[databases]
* = host=localhost port=5432
```

2. Enable and activate pgbouncer:

```
systemctl enable --now pgbouncer
```

### Configuring PAM

1. In the `/etc/pam.d/` directory, create a separate `pgbouncer` configuration with the following content:

```
#!/PAM-1.0
auth required pam_ldap.so
account required pam_ldap.so
```

Parameter descriptions:

- in the `auth required pam_ldap.so` entry:
  - `auth` is the authentication phase where the user password is verified.
  - `required` is a control flag. It means that if the module returns an error, the authentication fails. However, if successful, execution of other lines continues (i.e., early exit is not allowed).
  - `pam_ldap.so` is the module that communicates with LDAP and validates the specified username and password.
- in the `account required pam_ldap.so` entry:
  - `account` is the authorization or account phase where the system checks whether the user is permitted to log in. The account must be in the correct OU, must not be expired or locked.
  - `required` is a control flag. It means that if LDAP returns the “account invalid” error, the authentication fails.
  - `pam_ldap.so` is the same LDAP module. However, here it is used for password verification rather than for account state check.

2. Configure the module configuration file located at `/etc/pam_ldap.conf`. The configuration example looks as follows:

```
host ldap_server
base CN=Users,DC=postgrespro,DC=ru
binddn CN=service_user,CN=Users,DC=postgrespro,DC=ru
bindpw service_user_password
timelimit 5
bind_timelimit 5
```

pam\_login\_attribute CN

#### Parameter descriptions:

- `host` is the LDAP server(s) the client connects to.
- `base` is the base DN (distinguished name) where all search queries in the directory begin.
- `binddn` is the DN of the service account used by PAM to connect to LDAP for user searches.
- `bindpw` is the password for the `binddn` account.
- `timelimit` is the time limit (in seconds) for executing LDAP queries.
- `bind_timelimit` is the timeout (in seconds) for binding with the LDAP server.
- `pam_login_attribute` is the attribute of the LDAP user entry that will be compared to the specified username.

### Testing Connection

1. Connect to your DBMS instance via LDAP:

```
psql -h 127.0.0.1 -U testuser -d postgres
```

2. Connect to your DBMS instance via pgbouncer:

```
psql -h 127.0.0.1 -U testuser -d postgres -p 6500
```

In both cases, the server log must display that LDAP is used as an authentication method.

### Options

`-d, --daemon`

Run in the background. Without it, the process will run in the foreground. In daemon mode, setting `pidfile` as well as `logfile` or `syslog` is required. No log messages will be written to `stderr` after going into the background.

#### Note

Does not work on Windows, pgbouncer needs to run as service there.

`-R, --reboot`

#### Note

This option is deprecated. Instead of this option use a rolling restart with multiple pgbouncer processes listening on the same port using `so_reuseport` instead.

Do an online restart. That means connecting to the running process, loading the open sockets from it, and then using them. If there is no active process, boot normally.

#### Note

Works only if OS supports Unix sockets and the `unix_socket_dir` is not disabled in configuration. Does not work on Windows. Does not work with TLS connections, they are dropped.

`-u user, --user user`

Switch to the given user on startup.

`-v, --verbose`

Increase verbosity. Can be used multiple times.

`-q, --quiet`

Be quiet: do not log to stderr. This does not affect logging verbosity, only that stderr is not to be used. For use in `init.d` scripts.

`-V, --version`

Show version.

`-h, --help`

Show short help.

`--regservice`

Win32: Register to run as Windows service. The `service_name` configuration parameter value is used as the name to register under.

`--unregservice`

Win32: Unregister Windows service.

## Admin Console

The console is available by connecting as normal to the database `pgbouncer`:

```
$ psql -p 6432 pgbouncer
```

Only users listed in the configuration parameters `admin_users` or `stats_users` are allowed to log in to the console. (Except when `auth_mode=any`, then any user is allowed in as a `stats_user`.)

Additionally, the user name `pgbouncer` is allowed to log in without password, if the login comes via the Unix socket and the client has same Unix user uid as the running process.

The admin console currently only supports the simple query protocol. Some drivers use the extended query protocol for all commands; these drivers will not work for this.

## Show Commands

The `SHOW` commands output information. Each command is described below.

### SHOW STATS

Shows statistics. In this and related commands, the total figures are since process start, the averages are updated every `stats_period`.

database

Statistics are presented per database.

`total_xact_count`

Total number of SQL transactions pooled by pgbouncer.

`total_query_count`

Total number of SQL queries pooled by pgbouncer.

`total_received`

Total volume in bytes of network traffic received by pgbouncer.

`total_sent`

Total volume in bytes of network traffic sent by pgbouncer.

`total_xact_time`

Total number of microseconds spent by pgbouncer when connected to Postgres Pro in a transaction, either idle in transaction or executing queries.

`total_query_time`

Total number of microseconds spent by pgbouncer when actively connected to Postgres Pro, executing queries.

`total_wait_time`

Time spent by clients waiting for a server, in microseconds. Updated when a client connection is assigned a backend connection.

`avg_xact_count`

Average transactions per second in last stat period.

`avg_query_count`

Average queries per second in last stat period.

`avg_recv`

Average received (from clients) bytes per second.

`avg_sent`

Average sent (to clients) bytes per second.

`avg_xact_time`

Average transaction duration, in microseconds.

`avg_query_time`

Average query duration, in microseconds.

`avg_wait_time`

Average time spent by clients waiting for a server that were assigned a backend connection within the current `stats_period`, in microseconds (average per second within that period).

#### **SHOW STATS\_TOTALS**

Subset of `SHOW STATS` showing the total values (`total_`).

#### **SHOW STATS\_AVERAGES**

Subset of `SHOW STATS` showing the average values (`avg_`).

#### **SHOW TOTALS**

Like `SHOW STATS` but aggregated across all databases.

#### **SHOW SERVERS**

`type`

S, for server.

`user`

User name pgbouncer uses to connect to server.

`database`

Database name.

state

State of the pgbouncer server connection, one of `active`, `idle`, `used`, `tested`, `new`, `active_cancel`, or `being_canceled`.

addr

IP address of Postgres Pro server.

port

Port of Postgres Pro server.

local\_addr

Connection start address on local machine.

local\_port

Connection start port on local machine.

connect\_time

When the connection was made.

request\_time

When last request was issued.

wait

Not used for server connections.

wait\_us

Not used for server connections.

close\_needed

1 if the connection will be closed as soon as possible, because a configuration file reload or DNS update changed the connection information or `RECONNECT` was issued.

ptr

Address of internal object for this connection. Used as unique ID.

link

Address of client connection the server is paired with.

remote\_pid

PID of backend server process. In case connection is made over Unix socket and OS supports getting process ID info, its OS PID. Otherwise it's extracted from cancel packet the server sent, which should be the PID in case the server is Postgres Pro, but it's a random number in case the server is another pgbouncer.

tls

A string with TLS connection information, or empty if not using TLS.

application\_name

A string containing the `application_name` set on the linked client connection, or empty if this is not set, or if there is no linked connection.

## SHOW CLIENTS

type

C, for client.

user

Client connected user.

database

Database name.

state

State of the client connection, one of `active`, `waiting`, `active_cancel_req`, or `waiting_cancel_req`.

addr

IP address of the client.

port

Source port of the client.

local\_addr

Connection end address on local machine.

local\_port

Connection end port on local machine.

connect\_time

Timestamp of connect time.

request\_time

Timestamp of latest client request.

wait

Current waiting time in seconds.

wait\_us

Microsecond part of the current waiting time.

close\_needed

Not used for clients.

ptr

Address of internal object for this connection. Used as unique ID.

link

Address of server connection the client is paired with.

remote\_pid

Process ID, in case client connects over Unix socket and OS supports getting it.

tls

A string with TLS connection information, or empty if not using TLS.

application\_name

A string containing the `application_name` set by the client for this connection, or empty if this is not set.

## SHOW POOLS

A new pool entry is made for each couple of (database, user).

database

Database name.

user

User name.

cl\_active

Client connections that are either linked to server connections or are idle with no queries waiting to be processed.

cl\_waiting

Client connections that have sent queries but have not yet got a server connection.

cl\_active\_cancel\_req

Client connections that have forwarded query cancellations to the server and are waiting for the server response.

cl\_waiting\_cancel\_req

Client connections that have not forwarded query cancellations to the server yet.

sv\_active

Server connections that are linked to a client.

sv\_active\_cancel

Server connections that are currently forwarding a cancel request.

sv\_being\_canceled

Servers that normally could become idle but are waiting to do so until all in-flight cancel requests have completed that were sent to cancel a query on this server.

sv\_idle

Server connections that are unused and immediately usable for client queries.

sv\_used

Server connections that have been idle for more than `server_check_delay`, so they need `server_check_query` to run on them before they can be used again.

sv\_tested

Server connections that are currently running either `server_reset_query` or `server_check_query`.

sv\_login

Server connections currently in the process of logging in.

maxwait

How long the first (oldest) client in the queue has waited, in seconds. If this starts increasing, then the current pool of servers does not handle requests quickly enough. The reason may be either an overloaded server or just too small of a `pool_size` setting.

maxwait\_us

Microsecond part of the maximum waiting time.

pool\_mode

The pooling mode in use.

#### **SHOW PEER\_POOLS**

A new `peer_pool` entry is made for each configured peer.

database

ID of the configured peer entry.

cl\_active\_cancel\_req

Client connections that have forwarded query cancellations to the server and are waiting for the server response.

cl\_waiting\_cancel\_req

Client connections that have not forwarded query cancellations to the server yet.

sv\_active\_cancel

Server connections that are currently forwarding a cancel request.

sv\_login

Server connections currently in the process of logging in.

#### **SHOW LISTS**

Show following internal information, in columns (not rows):

databases

Count of databases.

users

Count of users.

pools

Count of pools.

free\_clients

Count of free clients.

used\_clients

Count of used clients.

login\_clients

Count of clients in `login` state.

free\_servers

Count of free servers.

used\_servers

Count of used servers.

dns\_names

Count of DNS names in the cache.

`dns_zones`

Count of DNS zones in the cache.

`dns_queries`

Count of in-flight DNS queries.

`dns_pending`

Not used.

#### **SHOW USERS**

`name`

The user name.

`pool_mode`

The user's override `pool_mode`, or `NULL` if the default will be used instead.

#### **SHOW DATABASES**

`name`

Name of configured database entry.

`host`

Host pgbouncer connects to.

`port`

Port pgbouncer connects to.

`database`

Actual database name pgbouncer connects to.

`force_user`

When the user is part of the connection string, the connection between pgbouncer and Postgres Pro is forced to the given user, whatever the client user.

`pool_size`

Maximum number of server connections.

`min_pool_size`

Minimum number of server connections.

`reserve_pool`

Maximum number of additional connections for this database.

`pool_mode`

The database's override `pool_mode`, or `NULL` if the default will be used instead.

`max_connections`

Maximum number of allowed connections for this database, as set by `max_db_connections`, either globally or per database.

`current_connections`

Current number of connections for this database.

paused

1 if this database is currently paused, else 0.

disabled

1 if this database is currently disabled, else 0.

#### SHOW PEERS

peer\_id

ID of the configured peer entry.

host

Host pgbouncer connects to.

port

Port pgbouncer connects to.

pool\_size

Maximum number of server connections that can be made to this peer.

#### SHOW FDS

Internal command — shows list of file descriptors (FDs) in use with internal state attached to them.

When the connected user has the user name `pgbouncer`, connects through the Unix socket and has the same UID as the running process, the actual FDs are passed over the connection. This mechanism is used to do an online restart.

#### Note

This does not work on Windows.

This command also blocks the internal event loop, so it should not be used while pgbouncer is in use.

fd

File descriptor numeric value.

task

One of `pooler`, `client` or `server`.

user

User of the connection using the FD.

database

Database of the connection using the FD.

addr

IP address of the connection using the FD, `unix` if a Unix socket is used.

port

Port used by the connection using the FD.

cancel

Cancel key for this connection.

link

File descriptor for corresponding server/client. NULL if idle.

#### **SHOW SOCKETS, SHOW ACTIVE\_SOCKETS**

Shows low-level information about sockets or only active sockets. This includes the information shown under `SHOW CLIENTS` and `SHOW SERVERS` as well as other more low-level information.

#### **SHOW CONFIG**

Show the current configuration settings, one per row, with the following columns:

key

Configuration variable name.

value

Configuration value.

default

Configuration default value.

changeable

Either `yes` or `no`, shows if the variable can be changed while running. If `no`, the variable can be changed only at boot-time. Use `SET` to change a variable at run time.

#### **SHOW MEM**

Shows low-level information about the current sizes of various internal memory allocations. The information presented is subject to change.

#### **SHOW DNS\_HOSTS**

Show host names in DNS cache.

hostname

Host name.

ttd

How many seconds until next lookup.

addrs

Comma separated list of addresses.

#### **SHOW DNS\_ZONES**

Show DNS zones in cache.

zonename

Zone name.

serial

Current serial.

count

Host names belonging to this zone.

#### **SHOW VERSION**

Show the pgbouncer version string.

**SHOW STATE**

Show the pgbouncer state settings. Current states are active, paused and suspended.

**Process Controlling Commands****PAUSE [db]**

pgbouncer tries to disconnect from all servers. Disconnecting each server connection waits for that server connection to be released according to the server pool's pooling mode (in transaction pooling mode, the transaction must complete, in statement mode, the statement must complete, and in session pooling mode the client must disconnect). The command will not return before all server connections have been disconnected. To be used at the time of database restart.

If database name is given, only that database will be paused.

New client connections to a paused database will wait until `RESUME` is called.

**DISABLE db**

Reject all new client connections on the given database.

**ENABLE db**

Allow new client connections after a previous `DISABLE` command.

**RECONNECT db**

Close each open server connection for the given database, or all databases, after it is released (according to the pooling mode), even if its lifetime is not up yet. New server connections can be made immediately and will connect as necessary according to the pool size settings.

This command is useful when the server connection setup has changed, for example to perform a gradual switchover to a new server. It is not necessary to run this command when the connection string in `pgbouncer.ini` has been changed and reloaded (see `RELOAD`) or when DNS resolution has changed, because then the equivalent of this command will be run automatically. This command is only necessary if something downstream of pgbouncer routes the connections.

After this command is run, there could be an extended period where some server connections go to an old destination and some server connections go to a new destination. This is likely only sensible when switching read-only traffic between read-only replicas, or when switching between nodes of a multimaster replication setup. If all connections need to be switched at the same time, `PAUSE` is recommended instead. To close server connections without waiting (for example, in emergency failover rather than gradual switchover scenarios), also consider `KILL`.

**KILL db**

Immediately drop all client and server connections on given database.

New client connections to a killed database will wait until `RESUME` is called.

**SUSPEND**

All socket buffers are flushed and pgbouncer stops listening for data on them. The command will not return before all buffers are empty. To be used at the time of pgbouncer online reboot.

New client connections to a suspended database will wait until `RESUME` is called.

**RESUME [db]**

Resume work from previous `KILL`, `PAUSE`, or `SUSPEND` command.

**SHUTDOWN**

The pgbouncer process will exit.

## RELOAD

The pgbouncer process will reload its configuration files and update changeable settings. This includes the main configuration file as well as the files specified by the settings `auth_file` and `auth_hba_file`.

pgbouncer notices when a configuration file reload changes the connection parameters of a database definition. An existing server connection to the old destination will be closed when the server connection is next released (according to the pooling mode), and new server connections will immediately use the updated connection parameters.

## WAIT\_CLOSE [*db*]

Wait until all server connections, either of the specified database or of all databases, have cleared the `close_needed` state (see [the section called “SHOW SERVERS”](#)). This can be called after a `RECONNECT` or `RELOAD` to wait until the respective configuration change has been fully activated, for example in switchover scripts.

## Other Commands

### SET *key* = *arg*

Changes a configuration setting (see also [the section called “SHOW CONFIG”](#)). For example:

```
SET log_connections = 1;
SET server_check_query = 'select 2';
```

(Note that this command is run on the pgbouncer admin console and sets pgbouncer settings. A `SET` command run on another database will be passed to the Postgres Pro backend like any other SQL command.)

## Signals

SIGHUP

Reload config. Same as issuing the command `RELOAD` on the console.

SIGINT

Safe shutdown. Same as issuing `PAUSE` and `SHUTDOWN` on the console.

SIGTERM

Immediate shutdown. Same as issuing `SHUTDOWN` on the console.

SIGUSR1

Same as issuing `PAUSE` on the console.

SIGUSR2

Same as issuing `RESUME` on the console.

## Libevent Settings

From the libevent documentation:

It is possible to disable support for `epoll`, `kqueue`, `devpoll`, `poll`, or `select` by setting the environment variable `EVENT_NOEPOLL`, `EVENT_NOKQUEUE`, `EVENT_NODEVPOLL`, `EVENT_NOPOLL` or `EVENT_NOSELECT`, respectively.

By setting the environment variable `EVENT_SHOW_METHOD`, libevent displays the kernel notification method that it uses.

## pgbouncer.ini Configuration File

The configuration file is in the `.ini` format. Section names are between `[` and `]`. Lines starting with `;` or `#` are taken as comments and ignored. The characters `;` and `#` are not recognized as special when they appear later in the line.

## Generic Settings

### logfile

Specifies the log file. For daemonization (`-d`), either this or `syslog` has to be set. The log file is kept open, so after rotation, `kill -HUP` or on console `RELOAD`; should be done. On Windows, the service must be stopped and started.

Note that setting `logfile` does not by itself turn off logging to `stderr`. Use the command-line option `-q` or `-d` for that.

Default: not set

### pidfile

Specifies the PID file. Without `pidfile` set, daemonization (`-d`) is not allowed.

Default: not set

### listen\_addr

Specifies a list (comma-separated) of addresses where to listen for TCP connections. You may also use `*` meaning "listen on all addresses". When not set, only Unix socket connections are accepted.

Addresses can be specified numerically (IPv4/IPv6) or by name.

Default: not set

### listen\_port

Which port to listen on. Applies to both TCP and Unix sockets.

Default: 6432

### unix\_socket\_dir

Specifies the location for Unix sockets. Applies to both the listening socket and server connections. If set to an empty string, Unix sockets are disabled. A value that starts with `@` specifies that a Unix socket in the abstract namespace should be created (currently supported on Linux and Windows).

For online reboot (`-R`) to work, a Unix socket needs to be configured, and it needs to be in the file-system namespace.

Default: `/tmp` (empty on Windows)

### unix\_socket\_mode

File system mode for Unix socket. Ignored for sockets in the abstract namespace. Not supported on Windows.

Default: 0777

### unix\_socket\_group

Group name to use for Unix socket. Ignored for sockets in the abstract namespace. Not supported on Windows.

Default: not set

### user

If set, specifies the Unix user to change to after startup. Works only if `pgbouncer` is started as root or if it's already running as the given user.

Not supported on Windows.

Default: not set

#### `pool_mode`

Specifies when a server connection can be reused by other clients.

#### `session`

Server is released back to pool after client disconnects. Default.

#### `transaction`

Server is released back to pool after transaction finishes.

#### `statement`

Server is released back to pool after query finishes. Transactions spanning multiple statements are disallowed in this mode.

#### `max_client_conn`

Maximum number of client connections allowed.

When this setting is increased, then the file descriptor limits in the operating system might also have to be increased. Note that the number of file descriptors potentially used is more than `max_client_conn`. If each user connects under its own username to the server, the theoretical maximum used is:

`max_client_conn + (max pool_size * total databases * total users)`

If a database user is specified in the connection string (all users connect under the same user name), the theoretical maximum is:

`max_client_conn + (max pool_size * total databases)`

The theoretical maximum should never be reached, unless somebody deliberately crafts a special load for it. Still, it means you should set the number of file descriptors to a safely high number.

Search for `ulimit` in your favorite shell man page. Note: `ulimit` does not apply in a Windows environment.

Default: 100

#### `default_pool_size`

How many server connections to allow per user/database pair. Can be overridden in the per-database configuration.

Default: 20

#### `min_pool_size`

Add more server connections to pool if below this number. Improves the behavior when the normal load suddenly comes back after a period of total inactivity. The value is effectively capped at the pool size.

Default: 0 (disabled)

#### `reserve_pool_size`

How many additional connections to allow to a pool (see [reserve\\_pool\\_timeout](#)). The 0 value disables this parameter.

Default: 0 (disabled)

#### `reserve_pool_timeout`

If a client has not been serviced in this time, `pgbouncer` enables use of additional connections from the reserve pool. The 0 value disables this parameter. [seconds]

Default: 5.0

#### `max_db_connections`

Do not allow more than this many server connections per database (regardless of user). This considers the pgbouncer database that the client has connected to, not the Postgres Pro database of the outgoing connection. This can also be set per database in the `[databases]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

#### `max_user_connections`

Do not allow more than this many server connections per user (regardless of database). This considers the pgbouncer user that is associated with a pool, which is either the user specified for the server connection or in absence of that the user the client has connected as. This can also be set per user in the `[users]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

#### `server_round_robin`

By default, pgbouncer reuses server connections in LIFO (last-in, first-out) manner, so that few connections get the most load. This gives best performance if you have a single server serving a database. But if there is a round-robin system behind a database address (TCP, DNS, or host list), then it is better if pgbouncer also uses connections in that manner, thus achieving uniform load.

Default: 0

#### `track_extra_parameters`

By default, pgbouncer tracks `client_encoding`, `datestyle`, `timezone`, `standard_conforming_strings` and `application_name` parameters per client. To allow other parameters to be tracked, they can be specified here, so that pgbouncer knows that they should be maintained in the client variable cache and restored in the server whenever the client becomes active.

If you need to specify multiple values, use a comma-separated list (e.g. `default_transaction_read-only, IntervalStyle`)

### Note

Most parameters cannot be tracked this way. The only parameters that can be tracked are ones that Postgres Pro reports to the client. Postgres Pro has [an official list of parameters that it reports to the client](#). Postgres Pro extensions can change this list though, they can add parameters themselves that they also report, and they can start reporting already existing parameters that Postgres Pro does not report. Notably Citus 12.0+ causes PostgreSQL to also report `search_path`.

The `postgres` protocol allows specifying parameter settings, both directly as a parameter in the startup packet, or inside the [options startup packet](#). Parameters specified using both of these methods are supported by `track_extra_parameters`. However, it's not possible to include `options` itself in `track_extra_parameters`, only the parameters contained in `options`.

Default: `IntervalStyle`

`ignore_startup_parameters`

By default, `pgbouncer` allows only parameters it can keep track of in startup packets: `client_encoding`, `datestyle`, `timezone` and `standard_conforming_strings`.

All other parameters will raise an error. To allow other parameters, they can be specified here, so that `pgbouncer` knows that they are handled by the admin and it can ignore them.

If you need to specify multiple values, use a comma-separated list (e.g. `options,extra_float_digits`).

The `postgres` protocol allows specifying parameter settings, both directly as a parameter in the startup packet, or inside the [options startup packet](#). Parameters specified using both of these methods are supported by `ignore_startup_parameters`. It's even possible to include `options` itself in `ignore_startup_parameters`, which results in any unknown parameters contained inside `options` to be ignored.

Default: empty

`peer_id`

The peer ID used to identify this `pgbouncer` process in a group of `pgbouncer` processes that are peered together. The `peer_id` value should be unique within a group of peered `pgbouncer` processes. When set to 0, `pgbouncer` peering is disabled. See also [\[peers\] Section](#) for more information. The maximum value that can be used for the `peer_id` is 16383.

Default: 0

`disable_pqexec`

Disable the Simple Query protocol (PQexec). Unlike the Extended Query protocol, Simple Query allows multiple queries in one packet, which allows some classes of SQL-injection attacks. Disabling it can improve security. Obviously, this means only clients that exclusively use the Extended Query protocol will stay working.

Default: 0

`application_name_add_host`

Add the client host address and port to the application name setting set on connection start. This helps in identifying the source of bad queries, etc. This logic applies only at the start of a connection. If `application_name` is later changed with `SET`, `pgbouncer` does not change it again.

Default: 0

`conffile`

Show location of current configuration file. Changing it will make `pgbouncer` use another configuration file for next `RELOAD` / `SIGHUP`.

Default: file from command line

`service_name`

Used on win32 service registration.

Default: `pgbouncer`

`job_name`

Alias for [service\\_name](#).

stats\_period

Sets how often the averages shown in various `SHOW` commands are updated and how often aggregated statistics are written to the log (but see [log\\_stats](#)). [seconds]

Default: 60

### Authentication Settings

pgbouncer handles its own client authentication and has its own database of users. These settings control this.

auth\_type

How to authenticate users.

cert

The client must connect over TLS connection with a valid client certificate. The user name is then taken from the `CommonName` field from the certificate.

md5

Use MD5-based password check. This is the default authentication method. [auth\\_file](#) may contain both MD5-encrypted and plain-text passwords. If `md5` is configured and a user has a SCRAM secret, then SCRAM authentication is used automatically instead.

scram-sha-256

Use password check with SCRAM-SHA-256. [auth\\_file](#) has to contain SCRAM secrets or plain-text passwords. Note that SCRAM secrets can only be used for verifying the password of a client but not for logging into a server. To be able to use SCRAM on server connections, use plain-text passwords.

plain

The clear-text password is sent over the wire. Deprecated.

trust

No authentication is done. The user name must still exist in [auth\\_file](#).

any

Like the `trust` method, but the user name given is ignored. Requires that all databases are configured to log in as a specific user. Additionally, the console database allows any user to log in as admin.

hba

The actual authentication type is loaded from [auth\\_hba\\_file](#). This allows different authentication methods for different access paths, for example: connections over Unix socket use `peer` authentication method, connections over TCP must use TLS.

pam

Pluggable Authentication Modules (PAM) method is used to authenticate users, [auth\\_file](#) is ignored. This method is not compatible with databases using the [auth\\_user](#) option. The service name reported to PAM is `pgbouncer`. `pam` is not supported in the HBA configuration file.

auth\_hba\_file

HBA configuration file to use when [auth\\_type](#) is `hba`.

Default: not set

#### auth\_file

The name of the file to load user names and passwords from. See [the section called “Authentication File Format”](#) for details.

Most authentication types (see [auth\\_type](#)) require that either [auth\\_file](#) or [auth\\_user](#) be set; otherwise there would be no users defined.

Default: not set

#### auth\_user

If [auth\\_user](#) is set, then any user not specified in [auth\\_file](#) will be queried through the [auth\\_query](#) query from `pg_shadow` in the database, using [auth\\_user](#). The password of [auth\\_user](#) will be taken from [auth\\_file](#). (If [auth\\_user](#) does not require a password, then it does not need to be defined in [auth\\_file](#).)

Direct access to `pg_shadow` requires admin rights. It's preferable to use a non-superuser that calls a `SECURITY DEFINER` function instead.

Default: not set

#### auth\_query

Query to load user's password from database.

Direct access to `pg_shadow` requires admin rights. It's preferable to use a non-superuser that calls a `SECURITY DEFINER` function instead.

Note that the query is run inside the target database. So if a function is used, it needs to be installed into each database.

Default: `SELECT username, passwd FROM pg_shadow WHERE username=$1`

#### auth\_dbname

Database name in the [\[databases\]](#) section to be used for authentication purposes. This option can be either global or overridden in the connection string if this parameter is specified.

### Log Settings

#### syslog

Toggles syslog on/off. On Windows, the event log is used instead.

Default: 0

#### syslog\_ident

Under what name to send logs to syslog.

Default: `pgbouncer` (program name)

#### syslog\_facility

Under what facility to send logs to syslog. Possibilities: `auth`, `authpriv`, `daemon`, `user`, `local0-7`.

Default: `daemon`

#### log\_connections

Log successful logins.

Default: 1

#### log\_disconnections

Log disconnections with reasons.

Default: 1

#### log\_pooler\_errors

Log error messages the pooler sends to clients.

Default: 1

#### log\_stats

Write aggregated statistics into the log, every `stats_period`. This can be disabled if external monitoring tools are used to grab the same data from `SHOW` commands.

Default: 1

#### verbose

Increase verbosity. Mirrors the `-v` switch on the command line. For example, using `-v -v` on the command line is the same as `verbose=2`.

Default: 0

### Console Access Control

#### admin\_users

Comma-separated list of database users that are allowed to connect and run all commands on the console. Ignored when `auth_type` is `any`, in which case any user name is allowed in as admin.

Default: empty

#### stats\_users

Comma-separated list of database users that are allowed to connect and run read-only queries on the console. That means all `SHOW` commands except `SHOW FDS`.

Default: empty

### Connection Sanity Checks, Timeouts

#### server\_reset\_query

Query sent to server on connection release, before making it available to other clients. At that moment no transaction is in progress, so the value should not include `ABORT` or `ROLLBACK`.

The query is supposed to clean any changes made to the database session so that the next client gets the connection in a well-defined state. The default is `DISCARD ALL`, which cleans everything, but that leaves the next client no pre-cached state. It can be made lighter, e.g. `DEALLOCATE ALL` to just drop prepared statements, if the application does not break when some state is kept around.

When transaction pooling is used, the `server_reset_query` is not used, because in that mode, clients must not use any session-based features, since each transaction ends up in a different connection and thus gets a different session state.

Default: `DISCARD ALL`

#### server\_reset\_query\_always

Whether `server_reset_query` should be run in all pooling modes. When this setting is off (default), the `server_reset_query` will be run only in pools that are in sessions-pooling mode. Connections in transaction-pooling mode should not have any need for a reset query.

This setting is for working around broken setups that run applications that use session features over a transaction-pooled pgbouncer. It changes non-deterministic breakage to deterministic breakage: clients always lose their state after each transaction.

Default: 0

`server_check_delay`

How long to keep released connections available for immediate re-use, without running `server_check_query` on it. If 0 then the query is always run.

Default: 30.0

`server_check_query`

Simple do-nothing query to check if the server connection is alive.

If an empty string, then sanity checking is disabled.

Default: `select 1`

`server_fast_close`

Disconnect a server in session pooling mode immediately or after the end of the current transaction if it is in `close_needed` mode (set by `RECONNECT`, `RELOAD` that changes connection settings, or DNS change), rather than waiting for the session end. In statement or transaction pooling mode, this has no effect since that is the default behavior there.

If because of this setting a server connection is closed before the end of the client session, the client connection is also closed. This ensures that the client notices that the session has been interrupted.

This setting makes connection configuration changes take effect sooner if session pooling and long-running sessions are used. The downside is that client sessions are liable to be interrupted by a configuration change, so client applications will need logic to reconnect and reestablish session state. But note that no transactions will be lost, because running transactions are not interrupted, only idle sessions.

Default: 0

`server_lifetime`

The pooler will close an unused (not currently linked to any client connection) server connection that has been connected longer than this. Setting it to 0 means the connection is to be used only once, then closed. [seconds]

Default: 3600.0

`server_idle_timeout`

If a server connection has been idle more than this many seconds it will be closed. If 0 then timeout is disabled. [seconds]

Default: 600.0

`server_connect_timeout`

If connection and login don't finish in this amount of time, the connection will be closed. [seconds]

Default: 15.0

`server_login_retry`

If login to the server failed, because of failure to connect or from authentication, the pooler waits this much before retrying to connect. During the waiting interval, new clients trying to connect to the failing server will get an error immediately without another connection attempt. [seconds]

The purpose of this behavior is that clients don't unnecessarily queue up waiting for a server connection to become available if the server is not working. However, it also means that if a server is momentarily failing, for example during a restart or if the configuration was erroneous, then it will take at least this long until the pooler will consider connecting to it again. Planned events such as restarts should normally be managed using the `PAUSE` command to avoid this.

Default: 15.0

`client_login_timeout`

If a client connects but does not manage to log in in this amount of time, it will be disconnected. Mainly needed to avoid dead connections stalling `SUSPEND` and thus online restart. [seconds]

Default: 60.0

`autodb_idle_timeout`

If the automatically created (via `"*`") database pools have been unused this many seconds, they are freed. The negative aspect of that is that their statistics are also forgotten. [seconds]

Default: 3600.0

`dns_max_ttl`

How long DNS lookups can be cached. The actual DNS TTL is ignored. [seconds]

Default: 15.0

`dns_nxdomain_ttl`

How long DNS errors and `NXDOMAIN` DNS lookups can be cached. [seconds]

Default: 15.0

`dns_zone_check_period`

Period to check if a zone serial has changed.

`pgbouncer` can collect DNS zones from host names (everything after first dot) and then periodically check if the zone serial changes. If it notices changes, all host names under that zone are looked up again. If any host IP changes, its connections are invalidated.

Default: 0.0 (disabled)

`resolv_conf`

The location of a custom `resolv.conf` file. This is to allow specifying custom DNS servers and perhaps other name resolution options, independent of the global operating system configuration.

The parsing of the file is done by the DNS backend library, not `pgbouncer`, so see the library's documentation for details on allowed syntax and directives.

Default: empty (use operating system defaults)

## TLS Settings

`client_tls_sslmode`

TLS mode to use for connections from clients. TLS connections are disabled by default. When enabled, `client_tls_key_file` and `client_tls_cert_file` must be also configured to set up the key and certificate `pgbouncer` uses to accept client connections.

`disable`

Plain TCP. If client requests TLS, it's ignored. Default.

`allow`

If client requests TLS, it is used. If not, plain TCP is used. If the client presents a client certificate, it is not validated.

`prefer`

Same as `allow`.

`require`

The client must use TLS. If not, the client connection is rejected. If the client presents a client certificate, it is not validated.

`verify-ca`

Client must use TLS with valid client certificate.

`verify-full`

Same as `verify-ca`.

`client_tls_key_file`

Private key for pgbouncer to accept client connections.

Default: not set

`client_tls_cert_file`

Certificate for private key. Clients can validate it.

Default: not set

`client_tls_ca_file`

Root certificate file to validate client certificates.

Default: not set

`client_tls_protocols`

Which TLS protocol versions are allowed. Allowed values: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`. Shortcuts: `all` (`tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3`), `secure` (`tlsv1.2,tlsv1.3`), `legacy` (`all`).

Default: `secure`

`client_tls_ciphers`

Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: `default/secure`, `compat/legacy`, `insecure/all`, `normal`, `fast`.

Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`

`client_tls_ecdhcurve`

Elliptic Curve name to use for ECDH key exchanges.

Allowed values: `none` (DH is disabled), `auto` (256-bit ECDH), curve name.

Default: `auto`

`client_tls_dheparams`

DHE key exchange type.

Allowed values: `none` (DH is disabled), `auto` (2048-bit DH), `legacy` (1024-bit DH).

Default: `auto`

#### `server_tls_sslmode`

TLS mode to use for connections to Postgres Pro servers. The default mode is `prefer`.

`disable`

Plain TCP. TLS is not even requested from the server.

`prefer`

TLS connection is always requested first from Postgres Pro. If refused, the connection will be established over plain TCP. Server certificate is not validated. Default.

`require`

Connection must go over TLS. If server rejects it, plain TCP is not attempted. Server certificate is not validated.

`verify-ca`

Connection must go over TLS and server certificate must be valid according to `server_tls_ca_file`. Server host name is not checked against certificate.

`verify-full`

Connection must go over TLS and server certificate must be valid according to `server_tls_ca_file`. Server host name must match certificate information.

#### `server_tls_ca_file`

Root certificate file to validate Postgres Pro server certificates.

Default: not set

#### `server_tls_key_file`

Private key for pgbouncer to authenticate against Postgres Pro server.

Default: not set

#### `server_tls_cert_file`

Certificate for private key. Postgres Pro server can validate it.

Default: not set

#### `server_tls_protocols`

Which TLS protocol versions are allowed. Allowed values: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`. Shortcuts: `all` (`tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3`), `secure` (`tlsv1.2,tlsv1.3`), `legacy` (`all`).

Default: `secure`

#### `server_tls_ciphers`

Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: `default/secure`, `compat/legacy`, `insecure/all`, `normal`, `fast`.

Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`

### Dangerous Timeouts

Setting the following timeouts can cause unexpected errors.

#### `query_timeout`

Queries running longer than that are canceled. This should be used only with a slightly smaller server-side `statement_timeout`, to apply only for network problems. [seconds]

Default: 0.0 (disabled)

#### `query_wait_timeout`

Maximum time queries are allowed to spend waiting for execution. If the query is not assigned to a server during that time, the client is disconnected. The 0 value disables this parameter. If this is disabled, clients will be queued indefinitely. [seconds]

This setting is used to prevent unresponsive servers from grabbing up connections. It also helps when the server is down or rejects connections for any reason.

Default: 120.0

#### `cancel_wait_timeout`

Maximum time cancellation requests are allowed to spend waiting for execution. If the cancel request is not assigned to a server during that time, the client is disconnected. 0 disables. If this is disabled, cancel requests will be queued indefinitely. [seconds]

This setting is used to prevent a client locking up when a cancel cannot be forwarded due to the server being down.

Default: 10.0

#### `client_idle_timeout`

Client connections idling longer than this many seconds are closed. This should be larger than the client-side connection lifetime settings, and only used for network problems. [seconds]

Default: 0.0 (disabled)

#### `idle_transaction_timeout`

If a client has been in the “idle in transaction” state longer, it will be disconnected. [seconds]

Default: 0.0 (disabled)

#### `suspend_timeout`

How long to wait for buffer flush during `SUSPEND` or reboot (`-R`). A connection is dropped if the flush does not succeed. [seconds]

Default: 10

### Low-Level Network Settings

#### `pkt_buf`

Internal buffer size for packets. Affects size of TCP packets sent and general memory usage. Actual libpq packets can be larger than this, so no need to set it large.

Default: 4096

#### `max_packet_size`

Maximum size for Postgres Pro packets that pgbouncer allows through. One packet is either one query or one result set row. The full result set can be larger.

Default: 2147483647

#### `listen_backlog`

The value of the `backlog` argument for `listen()`. Determines how many new unanswered connection attempts are kept in the queue. When the queue is full, further new connections are dropped.

Default: 128

#### `sbuf_loopcnt`

How many times to process data on one connection, before proceeding. Without this limit, one connection with a big result set can stall pgbouncer for a long time. One loop processes one `pkt_buf` amount of data. 0 means no limit.

Default: 5

#### `so_reuseport`

Specifies whether to set the socket option `SO_REUSEPORT` on TCP listening sockets. On some operating systems, this allows running multiple pgbouncer instances on the same host listening on the same port and having the kernel distribute the connections automatically. This option is a way to get pgbouncer to use more CPU cores. (pgbouncer is single-threaded and uses one CPU core per instance.)

This setting has the desired effect on Linux. On systems that don't support the socket option at all, turning this setting on will result in an error.

Each pgbouncer instance on the same host needs different settings for at least `unix_socket_dir` and `pidfile`, as well as `logfile` if that is used. Also note that if you make use of this option, you can no longer connect to a specific pgbouncer instance via TCP/IP, which might have implications for monitoring and metrics collection.

To make sure query cancellations keep working, you should set up pgbouncer peering between the different pgbouncer processes. For details see the [peer\\_id configuration option](#) and the [\[peers\] configuration section](#). There's also an example that uses peering and `so_reuseport` in the [Examples section](#).

Default: 0

#### `tcp_defer_accept`

Sets the `TCP_DEFER_ACCEPT` socket option; see `man 7 tcp` for details. (This is a Boolean option: 1 means enabled. The actual value set if enabled is currently hardcoded to 45 seconds.)

This is currently only supported on Linux.

Default: 1 on Linux, otherwise 0

#### `tcp_socket_buffer`

Default: not set

#### `tcp_keepalive`

Turns on basic keepalive with OS defaults.

On Linux, the system defaults are `tcp_keepidle=7200`, `tcp_keepintvl=75`, `tcp_keepcnt=9`. They are probably similar on other operating systems.

Default: 1

#### `tcp_keepcnt`

Default: not set

`tcp_keepidle`

Default: not set

`tcp_keepintvl`

Default: not set

`tcp_user_timeout`

Sets the `TCP_USER_TIMEOUT` socket option. This specifies the maximum amount of time in milliseconds that transmitted data may remain unacknowledged before the TCP connection is forcibly closed. If set to 0, then operating system's default is used.

This is currently only supported on Linux.

Default: 0

### Section [databases]

The section [databases] defines the names of the databases that clients of pgbouncer can connect to and specifies where those connections will be routed. The section contains `key=value` lines like

```
dbname = connection string
```

where the key will be taken as a database name and the value as a connection string, consisting of `key=value` pairs of connection parameters, described below (similar to libpq, but the actual libpq is not used and the set of available features is different).

Example:

```
foodb = host=host1.example.com port=5432
bardb = host=localhost dbname=bazdb
```

The database name can contain characters `_0-9A-Za-z` without quoting. Names that contain other chars need to be quoted with standard SQL ident quoting: double quotes where `"` is taken as single quote.

The database name `pgbouncer` is reserved for the admin console and cannot be used as a key here.

\* acts as fallback database: if the exact name does not exist, its value is taken as connection string for the requested database. For example, if there is the following entry (and no other overriding entries):

```
* = host=foo
```

In this case, a connection to pgbouncer specifying a database `bar` will effectively behave as if the following entry exists (taking advantage of the default for `dbname` being the client-side database name):

```
bar = host=foo dbname=bar
```

Such automatically created database entries are cleaned up if they stay idle longer than the time specified by the `autodb_idle_timeout` parameter.

`dbname`

Destination database name.

Default: same as client-side database name

`host`

Host name or IP address to connect to. Host names are resolved at connection time, the result is cached per `dns_max_ttl` parameter. When a host name's resolution changes, existing server connections are automatically closed when they are released (according to the pooling mode), and new server connections immediately use the new resolution. If DNS returns several results, they are used in a round-robin manner.

If the value begins with `/`, then a Unix socket in the file-system namespace is used. If the value begins with `@`, then a Unix socket in the abstract namespace is used.

A comma-separated list of host names or addresses can be specified. In that case, connections are made in a round-robin manner. (If a host list contains host names that in turn resolve via DNS to multiple addresses, the round-robin systems operate independently. This is an implementation dependency that is subject to change.) Note that in a list, all hosts must be available at all times: there are no mechanisms to skip unreachable hosts or to select only available hosts from a list or similar. (This is different from what a host list in `libpq` means.) Also note that this only affects how the destinations of new connections are chosen. See also the setting `server_round_robin` for how clients are assigned to already established server connections.

#### Examples:

```
host=localhost
host=127.0.0.1
host=2001:0db8:85a3:0000:0000:8a2e:0370:7334
host=/var/run/postgresql
host=192.168.0.1,192.168.0.2,192.168.0.3
```

Default: not set, meaning to use a Unix socket

#### port

Default: 5432

#### user

If `user=` is set, all connections to the destination database will be done with the specified user, meaning that there will be only one pool for this database.

Otherwise `pgbouncer` logs into the destination database with the client user name, meaning that there will be one pool per user.

#### password

If no password is specified here, the password from the `auth_file` or `auth_query` will be used.

#### auth\_user

Override of the global `auth_user` setting, if specified.

#### pool\_size

Set the maximum size of pools for this database. If not set, the `default_pool_size` is used.

#### min\_pool\_size

Set the minimum pool size for this database. If not set, the global `min_pool_size` is used.

#### reserve\_pool

Set additional connections for this database. If not set, `reserve_pool_size` is used.

#### connect\_query

Query to be executed after a connection is established, but before allowing the connection to be used by any clients. If the query raises errors, they are logged but ignored otherwise.

#### pool\_mode

Set the pool mode specific to this database. If not set, the default `pool_mode` is used.

#### max\_db\_connections

Configure a database-wide maximum (i.e. all pools within the database will not have more than this many server connections).

`client_encoding`

Ask specific `client_encoding` from server.

`datestyle`

Ask specific `datestyle` from server.

`timezone`

Ask specific `timezone` from server.

### Section [users]

This section contains `key=value` lines like

```
user1 = settings
```

where the key will be taken as a user name and the value as a list of configuration settings specific for this user.

Example:

```
user1 = pool_mode=session
```

Only a few settings are available here.

`pool_mode`

Set the pool mode to be used for all connections from this user. If not set, the database or default `pool_mode` is used.

`max_user_connections`

Configure a maximum for the user (i.e. all pools with the user will not have more than this many server connections).

### Section [peers]

This section defines the peers that `pgbouncer` can forward cancellation requests to and where those cancellation requests will be routed.

`pgbouncer` processes can be peered together in a group by defining a `peer_id` value and a `[peers]` section in the configs of all the `pgbouncer` processes. These `pgbouncer` processes can then forward cancellation requests to the process that it originated from. This is needed to make cancellations work when multiple `pgbouncer` processes (possibly on different servers) are behind the same TCP load balancer. Cancellation requests are sent over different TCP connections than the query they are cancelling, so a TCP load balancer might send the cancellation request connection to a different process than the one that it was meant for. By peering them these cancellation requests eventually end up at the right process.

The section contains `key=value` lines like

```
peer_id = connection string
```

where the key will be taken as a `peer_id` and the value as a connection string, consisting of `key=value` pairs of connection parameters, described below (similar to `libpq`, but the actual `libpq` is not used and the set of available features is different).

Example:

```
1 = host=host1.example.com
```

```
2 = host=/tmp/pgbouncer-2 port=5555
```

### Note

For peering to work, the `peer_id` of each `pgbouncer` process in the group must be unique within the peered group. And the `[peers]` section should contain entries for each of those peer IDs. An

example can be found in the [Examples](#) section. It is allowed, but not necessary, for the `[peers]` section to contain the `peer_id` of the `pgbouncer` that the config is for. Such an entry will be ignored, but it is allowed to make config management easier. Because it allows using the exact same `[peers]` section for multiple configs.

#### host

Host name or IP address to connect to. Host names are resolved at connection time, the result is cached per `dns_max_ttl` parameter. If DNS returns several results, they are used in a round-robin manner. But in general it's not recommended to use a hostname that resolves to multiple IPs, because then the cancel request might still be forwarded to the wrong node and it would need to be forwarded again (which is only allowed up to three times).

If the value begins with `/`, then a Unix socket in the file-system namespace is used. If the value begins with `@`, then a Unix socket in the abstract namespace is used.

#### Examples:

```
host=localhost
host=127.0.0.1
host=2001:0db8:85a3:0000:0000:8a2e:0370:7334
host=/var/run/pgbouncer-1
```

#### port

Default: 6432

#### pool\_size

If not set, the `default_pool_size` is used.

### Include Directive

The `pgbouncer` configuration file can contain include directives, which specify another configuration file to read and process. This allows splitting the configuration file into physically separate parts. The include directives look like this:

```
%include filename
```

If the filename is not an absolute path, it is taken as relative to the current working directory.

### Authentication File Format

This section describes the format of the file specified by the `auth_file` setting. It is a text file in the following format:

```
"username1" "password" ...
"username2" "md5abcdef012342345" ...
"username2" "SCRAM-SHA-256$iterations:salt$storedkey:serverkey"
```

There should be at least two fields, surrounded by double quotes. The first field is the user name and the second is either a plain-text, a MD5-hashed password, or a SCRAM secret. `pgbouncer` ignores the rest of the line. Double quotes in a field value can be escaped by writing two double quotes.

Postgres Pro MD5-hashed password format:

```
"md5" + md5(password + username)
```

|                                      |      |       |      |          |      |      |      |            |          |
|--------------------------------------|------|-------|------|----------|------|------|------|------------|----------|
| So                                   | user | admin | with | password | 1234 | will | have | MD5-hashed | password |
| md545f2603610af569b6155c45067268c6b. |      |       |      |          |      |      |      |            |          |

Postgres Pro SCRAM secret format:

```
SCRAM-SHA-256$iterations:salt$storedkey:serverkey
```

The passwords or secrets stored in the authentication file serve two purposes. First, they are used to verify the passwords of incoming client connections, if a password-based authentication method is configured. Second, they are used as the passwords for outgoing connections to the backend server, if the backend server requires password-based authentication (unless the password is specified directly in the database's connection string). The latter works if the password is stored in plain text or MD5-hashed. SCRAM secrets can only be used for logging into a server if the client authentication also uses SCRAM, the pgbouncer database definition does not specify a user name, and the SCRAM secrets are identical in pgbouncer and the Postgres Pro server (same salt and iterations, not merely the same password). This is due to an inherent security property of SCRAM: the stored SCRAM secret cannot by itself be used for deriving login credentials.

The authentication file can be written by hand, but it's also useful to generate it from some other list of users and passwords. See `./etc/mkauth.py` for a sample script to generate the authentication file from the `pg_shadow` system table.

Alternatively, use `auth_query` instead of `auth_file` to avoid having to maintain a separate authentication file.

### HBA File Format

The location of the HBA file is specified by the setting `auth_hba_file`. It is only used if `auth_type` is set to `hba`.

The file follows the format of the Postgres Pro `pg_hba.conf` file described in [Section 20.1](#).

- Supported record types: `local`, `host`, `hostssl`, `hostnossl`.
- Database field: Supports `all`, `sameuser`, `@file`, multiple names. Not supported: `replication`, `samerole`, `samegroup`.
- User name field: Supports `all`, `@file`, multiple names. Not supported: `+groupname`.
- Address field: Supports `IPv4`, `IPv6`. Not supported: DNS names, domain prefixes.
- Auth-method field: Only methods supported by pgbouncer's `auth_type` are supported, plus `peer` and `reject`, but except `any` and `pam`, which only work globally. User name map (`map=`) parameter is not supported.

### Examples

Small example configuration:

```
[databases]
template1 = host=localhost dbname=template1 auth_user=someuser

[pgbouncer]
pool_mode = session
listen_port = 6432
listen_addr = localhost
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
stats_users = stat_collector
```

Database examples:

```
[databases]

; foodb over Unix socket
foodb =

; redirect bardb to bazdb on localhost
bardb = host=localhost dbname=bazdb
```

```
; access to destination database will go with single user
forcedb = host=localhost port=300 user=baz password=foo client_encoding=UNICODE
datestyle=ISO
```

**Example of a secure function for auth\_query:**

```
CREATE OR REPLACE FUNCTION pgbouncer.user_lookup(in i_username text, out uname text,
    out phash text)
RETURNS record AS $$
BEGIN
    SELECT username, passwd FROM pg_catalog.pg_shadow
    WHERE username = i_username INTO uname, phash;
    RETURN;
END; $$ LANGUAGE plpgsql SECURITY DEFINER;
REVOKE ALL ON FUNCTION pgbouncer.user_lookup(text) FROM public, pgbouncer;
GRANT EXECUTE ON FUNCTION pgbouncer.user_lookup(text) TO pgbouncer;
```

**Example configs for 2 peered pgbouncer processes to create a multi-core pgbouncer setup using [so\\_reuseport](#).**

**The config for the first process:**

```
[databases]
postgres = host=localhost dbname=postgres

[peers]
1 = host=/tmp/pgbouncer1
2 = host=/tmp/pgbouncer2

[pgbouncer]
listen_addr=127.0.0.1
auth_file=auth_file.conf
so_reuseport=1
unix_socket_dir=/tmp/pgbouncer1
peer_id=1
```

**The config for the second process:**

```
[databases]
postgres = host=localhost dbname=postgres

[peers]
1 = host=/tmp/pgbouncer1
2 = host=/tmp/pgbouncer2

[pgbouncer]
listen_addr=127.0.0.1
auth_file=auth_file.conf
so_reuseport=1
; only unix_socket_dir and peer_id are different
unix_socket_dir=/tmp/pgbouncer2
peer_id=2
```

## pg\_filedump

`pg_filedump` — display formatted contents of a Postgres Pro heap, index, or control file

### Synopsis

```
pg_filedump [option...] [file]
```

### Description

`pg_filedump` is a utility to format Postgres Pro heap/index/control files into a human-readable form. You can format/dump the files several ways, as listed in the [Options](#) section, as well as dump a straight binary. The type of file (heap/index) can usually be determined automatically by the content of the blocks within the file. However, to format a `pg_control` file you must use the `-c` option. The default is to format the entire file using the block size listed in block 0 and display block relative addresses. These defaults can be modified using run-time options. Some options may seem strange but they are there for a reason. For example, block size. It is there because if the header of block 0 is corrupt, you need a method of forcing a block size.

### Installation

`pg_filedump` is provided with Postgres Pro Enterprise as a separate pre-built package `pg-file-dump-ent-14` (for the detailed installation instructions, see [Chapter 17](#)).

### Options

Defaults are: relative addressing, range of the entire file, block size as listed on block 0 in the file.

The following options are valid for heap and index files:

- `-a`  
Display absolute addresses when formatting. Block header information is always block-relative.
- `-b`  
Display binary block images within a range. The option will turn off all formatting options.
- `-d`  
Display formatted block content dump. The option will turn off all other formatting options.
- `-D attrlist`  
Decode tuples using given comma-separated list of types. The list of supported types:  
  - `bigint`
  - `bigserial`
  - `bool`
  - `char`
  - `charN` — `char(n)`
  - `date`
  - `float`
  - `float4`
  - `float8`
  - `int`
  - `json`
  - `macaddr`
  - `name`
  - `numeric`
  - `oid`
  - `real`

```

serial
smallint
smallserial
text
time
timestamp
timetz
uuid
varchar
varcharN — varchar(n)
xid
xml
~ — ignore all attributes left in a tuple

```

- f  
Display formatted block content dump along with interpretation.
- h  
Display help.
- i  
Display interpreted item details.
- k  
Verify block checksums.
- o  
Do not dump old values.
- R *startblock* [*endblock*]  
Display specific block ranges within the file. Blocks are indexed from 0. *startblock*: block to start at. *endblock*: block to end at. A *startblock* without an *endblock* will format a single block.
- s *segsize*  
Force segment size to *segsize*.
- t  
Dump TOAST files.
- v  
Output additional information about TOAST relations.
- n *segnumber*  
Force segment number to *segnumber*.
- S *blocksize*  
Force block size to *blocksize*.
- x  
Force interpreted formatting of block items as index items.
- y  
Force interpreted formatting of block items as heap items.

The following options are valid for control files:

`-c`

Interpret the file listed as a control file.

`-f`

Display formatted content dump along with interpretation.

`-S blocksize`

Force block size to *blocksize*.

Additional parameters:

`-m`

Interpret file as `pg_filenode.map` file and print contents. All other options will be ignored.

In most cases, it is recommended to use the `-i` and `-f` options to get the most useful dump output.

# Appendix J. External Projects

Postgres Pro is a complex software project, and managing the project is difficult. We have found that many enhancements to Postgres Pro can be more efficiently developed separately from the core project.

## J.1. Client Interfaces

There are only two client interfaces included in the base Postgres Pro Enterprise distribution:

- [libpq](#) is included because it is the primary C language interface, and because many other client interfaces are built on top of it.
- [ECPG](#) is included because it depends on the server-side SQL grammar, and is therefore sensitive to changes in Postgres Pro itself.

All other language interfaces are external projects and are distributed separately. A [list of language interfaces](#) is maintained on the PostgreSQL wiki. Note that some of these packages are not released under the same license as Postgres Pro. For more information on each language interface, including licensing terms, refer to its website and documentation.

[https://wiki.postgresql.org/wiki/List\\_of\\_drivers](https://wiki.postgresql.org/wiki/List_of_drivers)

## J.2. Administration Tools

There are several administration tools available for Postgres Pro. One of them is [Postgres Pro Enterprise Manager](#), an integrated administration panel for Postgres Pro management. It provides centralized privilege-based access to a unified management and monitoring interface with embedded command line. There are other solutions, e.g. an open-source platform [pgAdmin](#).

## J.3. Procedural Languages

Postgres Pro includes several procedural languages with the base distribution: [PL/pgSQL](#), [PL/Tcl](#), [PL/Perl](#), and [PL/Python](#).

In addition, there are a number of procedural languages that are developed and maintained outside the core Postgres Pro distribution. A list of [procedural languages](#) is maintained on the PostgreSQL wiki. Note that some of these projects are not released under the same license as Postgres Pro. For more information on each procedural language, including licensing information, refer to its website and documentation.

[https://wiki.postgresql.org/wiki/PL\\_Matrix](https://wiki.postgresql.org/wiki/PL_Matrix)

## J.4. Extensions

Postgres Pro is designed to be easily extensible. For this reason, extensions loaded into the database can function just like features that are built in. The extensions shipped with Postgres Pro are described in [Appendix F](#). Other extensions are developed independently, like [PostGIS](#). Even Postgres Pro replication solutions can be developed externally. For example, [Slony-I](#) is a popular primary/standby replication solution that is developed independently from the core project.

---

# Appendix K. Configuring Postgres Pro for 1C Solutions

This section describes how to configure Postgres Pro for work with 1C solutions to get the maximum performance and stability.

## K.1. Configuring the Locale

Before configuring Postgres Pro for 1C solutions, make sure that the Russian locale is installed on the system and that it is the active locale of the user who creates the database cluster. The following example shows how to set up the `ru_RU.UTF-8` locale for Debian systems:

```
sudo dpkg-reconfigure locales
export LANG="ru_RU.UTF-8"
/opt/pgpro/ent-14/bin/pg-setup initdb
```

For more details, see related documentation sections for your operating system and for 1C.

## K.2. Basic Server Requirements and Configuration

To provide high performance for 1C solutions, the Postgres Pro server must have at least the following hardware characteristics:

- 8 - 512 GB of RAM
- 4 - 256 CPU cores
- RAID 0-1 or SSD

The exact recommended characteristics depend on your system's specifics and the load on it.

It is recommended to configure the Postgres Pro server as follows:

- Disable the hyper-threading technology.
- Disable energy saving. Otherwise, delays of database responses may increase unpredictably.
- Disable swapping for POSIX/System V shared memory.

## K.3. Configuring Server Parameters

This document describes how to specify configuration parameters of the Postgres Pro server for the maximum performance and stability when working with 1C solutions. Edit these parameters in the `postgresql.conf` configuration file. Note that all given parameter values are approximate. They can be considered as a starting point for further fine-tuning.

For fast automatic tuning of Postgres Pro, you can also use the [pgpro\\_tune](#) utility. It provides the `1c.tune` preset that specifies optimal values for 1C-specific configuration parameters. For detailed information about the usage of this utility, see [its documentation](#).

### K.3.1. Connection Parameters

Increase the maximum number of allowed concurrent connections to the database server using the [max\\_connections](#) configuration parameter. 1C solutions can open a large number of connections even if not all of them are used. Therefore, it is recommended to allow not less than 500 connections. The higher the number of client sessions, the higher the parameter value should be.

```
-- max_connections = 500..10000
```

### K.3.2. Memory Consumption Parameters

1. Increase the amount of memory allocated by the database for data caching. To do this, use the [shared\\_buffers](#) configuration parameter. For good performance, it is recommended to set this parameter to at least 25% of the available system RAM.

```
-- shared_buffers = RAM/4
```

2. Increase the maximum amount of memory used for temporary buffers within each database session to ensure that all temporary tables are handled correctly. To do this, use the [temp\\_buffers](#) configuration parameter.

The recommended value should be between 32MB and 256MB. The exact value depends on the amount of memory on the server and the number of concurrent connections. The more connections and the smaller the amount of memory, the smaller the parameter value should be.

```
-- temp_buffers = 32..256MB
```

3. Increase the maximum amount of memory to be used by a single query operation before writing to temporary disk files. To do this, use the [work\\_mem](#) configuration parameter.

When choosing the parameter value, note that a complex query might perform several sort and hash operations at the same time, and each of them can use the specified amount of memory. Also, several running sessions can perform such operations concurrently. Therefore, the total used memory can be many times greater than the specified value. You can fine-tune the parameter value by monitoring the number of temporary files created in the system.

```
-- work_mem = RAM/32..64 or 32MB..256MB
```

4. Increase the maximum amount of memory to be used by maintenance database operations, such as VACUUM or CREATE INDEX. To do this, use the [maintenance\\_work\\_mem](#) configuration parameter.

Note that only one of these operations can be executed at a time by a database session. Therefore, you can set this value significantly larger than `work_mem`. Larger values can improve performance for vacuuming and restoring database dumps.

```
-- maintenance_work_mem = RAM/16..32 or work_mem * 4 or 256MB..4GB
```

5. In the case of significant memory fragmentation, specify the following environment variable in the `/etc/systemd/system/postgresql.service` file:

```
-- Environment = MALLOC_MMAP_THRESHOLD_= 8192
```

### K.3.3. Kernel Resource Usage Parameters

Increase the maximum number of simultaneously open files allowed to each server subprocess. To do this, use the [max\\_files\\_per\\_process](#) configuration parameter.

The recommended value is 10000 but it can be increased depending on the load. The maximum allowed value depends on the operating system. If the server reaches the specified limit, it starts to open and close files, which affects the performance. You can monitor open files using the `lsof` command.

```
-- max_files_per_process = 10000
```

### K.3.4. Background Writer Parameters

1. Decrease the delay between activity rounds for the background writer using the [bgwriter\\_delay](#) configuration parameter. Note that a too high parameter value will increase the load on the checkpoint process and the backend processes, while a too low value will result in the full load of one of the cores.

```
-- bgwriter_delay = 20ms
```

2. Increase values for the [bgwriter\\_lru\\_multiplier](#) and [bgwriter\\_lru\\_maxpages](#) configuration parameters that control the number of dirty buffers written by the background writer in each round.

```
-- bgwriter_lru_multiplier = 4.0
-- bgwriter_lru_maxpages = 400
```

### K.3.5. Asynchronous Behavior Parameters

1. Specify the number of concurrent disk I/O operations that any individual Postgres Pro session attempts to initiate in parallel. To do this, use the [effective\\_io\\_concurrency](#) configuration parameter. Currently, this parameter affects bitmap heap scans only.

For magnetic drives, a good starting point for this parameter is the number of separate drives comprising a RAID 0 stripe or RAID 1 mirror used for the database. However, too high parameter values will keep the disk array busy, which results in extra CPU overhead.

SSD disks can often process many concurrent requests, so the best value might be in the hundreds.

```
-- effective_io_concurrency = 2
```

2. Set the [max\\_parallel\\_workers\\_per\\_gather](#) configuration parameter to 0. This disables parallel queries that can be started by `Gather` and `Gather Merge` nodes. Parallel queries may consume very significantly more resources than non-parallel queries.

```
-- max_parallel_workers_per_gather = 0
```

### K.3.6. WAL Parameters

1. Leave the [fsync](#) configuration parameter set to `on` (default). In this case, the Postgres Pro server tries to make sure that updates are physically written to disk by issuing the `fsync()` system calls. This ensures that the database cluster can recover to a consistent state after an operating system or hardware crash.

Although disabling the `fsync` parameter often leads to a performance benefit, this can result in unrecoverable data corruption in case of a power failure or system crash.

```
-- fsync = on
```

Important note: if your RAID has a cache and works in the write-back mode, make sure that the disk controller cache has a valid battery. Otherwise, data written to the cache will be lost in the case of a power failure, and the Postgres Pro server will be unable to recover the data.

2. Increase values for the [checkpoint\\_timeout](#), [min\\_wal\\_size](#), and [max\\_wal\\_size](#) configuration parameters to reduce the frequency of checkpoints. Too frequent checkpoints lead to the significant load on the disk system.

```
-- checkpoint_timeout = 15min
-- min_wal_size = 512MB..4G
-- max_wal_size = 2 * min_wal_size
```

3. Specify the [commit\\_delay](#) configuration parameter if the average number of transactions per second (TPS) exceeds 1000. This parameter adds a time delay before a WAL flush is initiated and can improve the group commit throughput.

```
-- commit_delay = 1000
```

### K.3.7. Query Planning Parameters

1. Specify the [effective\\_cache\\_size](#) configuration parameter to define the planner's assumption about the effective size of the disk cache that is available to a single query.

The query optimizer's performance depends on the amount of allocated RAM. A higher value makes it more likely index scans will be used, while a lower value results in using sequential scans.

```
-- effective_cache_size = RAM - shared_buffers
```

2. Specify the [random\\_page\\_cost](#) configuration parameter to define the planner's estimate of the cost of a non-sequentially-fetched disk page.

The parameter value is specified relative to the [seq\\_page\\_cost](#) parameter, which is set to 1.0 by default. Reducing the [random\\_page\\_cost](#) value will cause the system to prefer index scans to sequential scans. The recommended value depends on the seek time of the disk system. The smaller the seek time, the smaller the parameter value should be (but not less than 1.0).

```
-- random_page_cost = 1.5-2.0 (for RAID) or 1.1-1.3 (for SSD)
```

3. Increase the value for the [from\\_collapse\\_limit](#) configuration parameter. The planner will merge subqueries into upper queries if the resulting FROM list would have no more than this many items. Note that smaller parameter values reduce planning time but can lead to less efficient query plans.

```
-- from_collapse_limit = 20
```

4. Increase the value of the [join\\_collapse\\_limit](#) configuration parameter. The planner will rewrite explicit JOIN constructs (except FULL JOINS) into lists of FROM items whenever a list contains no more than this many items. Note that smaller parameter values reduce planning time but can lead to less efficient query plans.

```
-- join_collapse_limit = 20
```

5. Set the [enable\\_sorted\\_merge\\_join](#) configuration parameter to `off` to disable the use of merge joins in plans with sorting. 1C solutions do not work with merge joins, so the planner spends useless time to consider such joins when searching for an optimal plan. Disabling this parameter allows the planner to reduce planning time.

```
-- enable_sorted_merge_join = off
```

6. Leave the [geqo](#) configuration parameter set to `on` (default). This enables the genetic query optimizer (GEQO) that does query planning using the heuristic search. GEQO reduces planning time for complex queries joining many relations but sometimes may produce plans that are less efficient than plans chosen by the regular exhaustive-search algorithm.

To manage the use of GEQO, specify the [geqo\\_threshold](#) configuration parameter. GEQO will be used to plan queries that involve at least the specified number of FROM items.

```
-- geqo = on
-- geqo_threshold = 12
```

7. Set the [jit](#) configuration parameter to `off` to disable Just-in-Time (JIT) compilation. This compilation is beneficial primarily for long-running CPU-bound queries, such as analytical queries. For short queries, the added overhead will be higher than the time that JIT compilation can save.

```
-- jit = off
```

### K.3.8. Automatic Vacuuming Parameters

1. Leave the [autovacuum](#) configuration parameter set to `on` (default) to run the autovacuum launcher daemon. Note that disabling the autovacuum launcher daemon will lead to increasing the database size and significant performance degradation.

```
-- autovacuum = on
```

2. Increase the maximum number of autovacuum processes that may be running at the same time using the [autovacuum\\_max\\_workers](#) configuration parameter. The more write requests are executed in the system, the more autovacuum processes are required.

```
-- autovacuum_max_workers = CPU cores/4..2 (but no less than 4)
```

3. Decrease the minimum delay between autovacuum rounds using the [autovacuum\\_naptime](#) configuration parameter. If a parameter value is too high, there can be not enough time to clean the required

tables. This will lead to increasing the database size and significant performance degradation. However, a too low parameter value leads to the useless load.

```
-- autovacuum_naptime = 20s
```

### K.3.9. Client Connection Parameters

1. Specify the directory in which to create temporary tables and indexes on temporary tables using the `temp_tablespaces` configuration parameter. Typically, 1C solutions use a lot of temporary tables. To increase the performance when working with these tables, locate this directory on separate fast disks.

Before this, you should first create the tablespace using the `CREATE TABLESPACE` command. If characteristics of the target disks differ from the main disks, specify the corresponding value for the `random_page_cost` parameter in this command.

```
-- temp_tablespaces = 'tablespace_name'
```

2. Set the `row_security` configuration parameter to `off` to raise an error if a query's results are filtered by a `row-level security` policy.

```
-- row_security = off
```

### K.3.10. Lock Management Parameters

Increase the value for the `max_locks_per_transaction` configuration parameter up to 256. It specifies how many objects per server process or prepared transaction can be locked at the same time.

Typically, 1C solutions use a lot of temporary tables. Every backend process usually contains multiple temporary tables. When closing a connection, Postgres Pro tries to drop all temporary tables in a single transaction, so this transaction may use a lot of locks. If the number of locks exceeds the `max_locks_per_transaction` value, the transaction will fail leaving multiple orphaned temporary tables.

```
-- max_locks_per_transaction = 256
```

### K.3.11. Parameters for 1C Compatibility

1. Set the `standard_conforming_strings` configuration parameter to `off` to enable backslash escapes (`\`) in all strings.

```
-- standard_conforming_strings = off
```

2. Set the `escape_string_warning` configuration parameter to `off` to switch off the warning about using the backslash escape symbol.

```
-- escape_string_warning = off
```

### K.3.12. Path to `pg_stat_tmp` Subdirectory

Change the default path to the `PGDATA/pg_stat_tmp` subdirectory to locate it separately from the cluster directory. This subdirectory contains temporary files for the statistics subsystem. These files are changed intensively, which creates the significant load on the disk system. It is recommended to locate this subdirectory in `tmpfs` (temporary file storage).

## K.4. Additional Modules

### K.4.1. Built-In Default Modules

To provide support for 1C solutions, the Postgres Pro distribution includes the following built-in modules that are enabled by default and do not require additional configuration:

- `fasttrun` — provides a transaction-unsafe function to truncate temporary tables without growing the size of `pg_class`.

- [fulleq](#) — provides an additional equivalence operator for compatibility with Microsoft SQL Server.
- [mchar](#) — provides additional `MCHAR` and `MVARCHAR` data types for compatibility with Microsoft SQL Server.

## K.4.2. plantuner

The [plantuner](#) module allows optimizing query execution plans. To configure it for 1C solutions, do the following:

1. Add the library name to the `shared_preload_libraries` variable in the `postgresql.conf` file.

```
shared_preload_libraries = 'plantuner'
```

2. Set the `plantuner.fix_empty_table` parameter to `on` to improve planning for recently created empty tables.

```
plantuner.fix_empty_table = on
```

## K.4.3. online\_analyze

The [online\\_analyze](#) module provides a set of features that immediately update statistics after `INSERT`, `UPDATE`, `DELETE`, `SELECT INTO`, or `COPY` operations for the affected tables.

### Note

It is not recommended to use this module with modern versions of 1C.

However, you can enable `online_analyze` if background updates do not provide the desired result or if the optimizer frequently fails to estimate the row count.

The instruction below is relevant only if you decide to use the module.

To configure this module, follow the steps below.

1. Add the library name to the `shared_preload_libraries` variable in the `postgresql.conf` file.

```
shared_preload_libraries = 'online_analyze'
```

2. Enable this module.

```
online_analyze.enable = on
```

3. Specify the minimum number of row updates before starting online analysis.

```
online_analyze.threshold = 50
```

4. Specify the fraction of the table size to start online analysis.

```
online_analyze.scale_factor = 0.1
```

5. Execute the `ANALYZE` command without `VERBOSE`.

```
online_analyze.verbose = off
```

6. Enable online analysis for temporary tables.

```
online_analyze.table_type = 'temporary'
```

7. Specify the minimum time interval between `ANALYZE` calls per table, in milliseconds.

```
online_analyze.min_interval = 10000
```

### K.4.4. auto\_dump

The [auto\\_dump](#) extension is designed to collect data on long-running and problematic queries and to further reproduce these problems for troubleshooting.

To enable and configure this extension, do the following:

1. Add `auto_dump` to the [shared\\_preload\\_libraries](#) parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'auto_dump'
```

2. Enable the extension:

```
auto_dump.enable = on
```

Before using the extension, set other [required configuration parameters](#) and restart the database server for the changes to take effect.

---

# Appendix L. Postgres Pro Limits

[Table L.1](#) describes various hard limits of Postgres Pro. However, practical limits, such as performance limitations or available disk space may apply before absolute hard limits are reached.

**Table L.1. Postgres Pro Limitations**

| Item                    | Upper Limit                                                           | Comment                                                                |
|-------------------------|-----------------------------------------------------------------------|------------------------------------------------------------------------|
| database size           | unlimited                                                             |                                                                        |
| number of databases     | 4,294,950,911                                                         |                                                                        |
| relations per database  | 1,431,650,303                                                         |                                                                        |
| relation size           | 32 TB                                                                 | with the default <code>BLCKSZ</code> of 8192 bytes                     |
| rows per table          | limited by the number of tuples that can fit onto 4,294,967,295 pages |                                                                        |
| columns per table       | 1,600                                                                 | further limited by tuple size fitting on a single page; see note below |
| columns in a result set | 1,664                                                                 |                                                                        |
| field size              | 1 GB                                                                  |                                                                        |
| indexes per table       | unlimited                                                             | constrained by maximum relations per database                          |
| columns per index       | 32                                                                    | can be increased by recompiling Postgres Pro                           |
| partition keys          | 32                                                                    | can be increased by recompiling Postgres Pro                           |
| identifier length       | 63 bytes                                                              | can be increased by recompiling Postgres Pro                           |
| function arguments      | 100                                                                   | can be increased by recompiling Postgres Pro                           |
| query parameters        | 65,535                                                                |                                                                        |

The maximum number of columns for a table is further reduced as the tuple being stored must fit in a single 8192-byte heap page. For example, excluding the tuple header, a tuple made up of 1,600 `int` columns would consume 6400 bytes and could be stored in a heap page, but a tuple of 1,600 `bigint` columns would consume 12800 bytes and would therefore not fit inside a heap page. Variable-length fields of types such as `text`, `varchar`, and `char` can have their values stored out of line in the table's TOAST table when the values are large enough to require it. Only an 18-byte pointer must remain inside the tuple in the table's heap. For shorter length variable-length fields, either a 4-byte or 1-byte field header is used and the value is stored inside the heap tuple.

Columns that have been dropped from the table also contribute to the maximum column limit. Moreover, although the dropped column values for newly created tuples are internally marked as null in the tuple's null bitmap, the null bitmap also occupies space.

Each table can store a theoretical maximum of  $2^{32}$  out-of-line values; see [Section 70.2](#) for a detailed discussion of out-of-line storage. This limit arises from the use of a 32-bit OID to identify each such value. The practical limit is significantly less than the theoretical limit, because as the OID space fills up, finding an OID that is still free can become expensive, in turn slowing down INSERT/UPDATE statements. Typically, this is only an issue for tables containing many terabytes of data; partitioning is a possible workaround.

# Appendix M. Demo Database

## “Airlines”

This is an overview of a demo database for Postgres Pro. This appendix describes the database schema, which consists of eight tables and several views. The subject field of this database is airline flights in Russia. You can download the database from [our website](#). See [Section M.1](#) for details.

**Figure M.1. Airlines in Russia**

You can use this database for various purposes, such as:

- learning SQL language on your own
- preparing books, manuals, and courses on SQL
- showing Postgres Pro features in stories and articles

When developing this demo database, we pursued several goals:

- Database schema must be simple enough to be understood without extra explanations.
- At the same time, database schema must be complex enough to allow writing meaningful queries.
- The database must contain true-to-life data that will be interesting to work with.

This demo database is distributed under the [PostgreSQL license](#).

You can send us your feedback to [edu@postgrespro.ru](mailto:edu@postgrespro.ru).

## M.1. Installation

The demo database is available at [edu.postgrespro.com](http://edu.postgrespro.com) in three flavors, which differ only in the data size:

- [demo-small-en.zip](#) (21 MB) — flight data for one month (DB size is about 300 MB)
- [demo-medium-en.zip](#) (62 MB) — flight data for three months (DB size is about 700 MB)
- [demo-big-en.zip](#) (232 MB) — flight data for one year (DB size is about 2.5 GB)

The small database is good for writing queries, and it will not take up much disk space. The large database can help you understand the query behavior on large data volumes and consider query optimization.

The files include an SQL script that creates the `demo` database and fills it with data (virtually, it is a backup copy created with the `pg_dump` utility). The owner of the `demo` database will be the DBMS user who runs the script. For example, to create the small database, run the script as the user `postgres` by means of `psql`:

```
psql -f demo_small_YYYYMMDD.sql -U postgres
```

Note that if the `demo` database already exists, it will be deleted and recreated!

## M.2. Schema Diagram

**Figure M.2. Bookings Schema Diagram**

## M.3. Schema Description

The main entity is a booking (`bookings`).

One booking can include several passengers, with a separate ticket (`tickets`) issued to each passenger. A ticket has a unique number and includes information about the passenger. As such, the passenger is not a separate entity. Both the passenger's name and identity document number can change over time, so it is impossible to uniquely identify all the tickets of a particular person; for simplicity, we can assume that all passengers are unique.

The ticket includes one or more flight segments (`ticket_flights`). Several flight segments can be included into a single ticket if there are no non-stop flights between the points of departure and destination (connecting flights), or if it is a round-trip ticket. Although there is no constraint in the schema, it is assumed that all tickets in the booking have the same flight segments.

Each flight (`flights`) goes from one airport (`airports`) to another. Flights with the same flight number have the same points of departure and destination, but differ in departure date.

At flight check-in, the passenger is issued a boarding pass (`boarding_passes`), where the seat number is specified. The passenger can check in for the flight only if this flight is included into the ticket. The flight-seat combination must be unique to avoid issuing two boarding passes for the same seat.

The number of seats (`seats`) in the aircraft and their distribution between different travel classes depends on the model of the aircraft (`aircrafts`) performing the flight. It is assumed that every aircraft model has only one cabin configuration. Database schema does not check that seat numbers in boarding passes have the corresponding seats in the aircraft (such verification can be done using table triggers, or at the application level).

## M.4. Schema Objects

### M.4.1. List of Relations

| Name                         | Type  | Small | Medium | Big    | Description             |
|------------------------------|-------|-------|--------|--------|-------------------------|
| <code>aircrafts</code>       | view  |       |        |        | Aircraft                |
| <code>aircrafts_data</code>  | table | 16 kB | 16 kB  | 16 kB  | Aircraft (translations) |

### M.4.2. View `bookings.aircrafts`

Each aircraft model is identified by its three-digit code (`aircraft_code`). The view also includes the name of the aircraft model (`model`) and the maximal flying distance, in kilometers (`range`).

The value of the `model` field is selected according to the chosen language. See [Section M.4.15](#) for details.

| Column                     | Type                 | Modifiers             | Description                 |
|----------------------------|----------------------|-----------------------|-----------------------------|
| <code>aircraft_code</code> | <code>char(3)</code> | <code>not null</code> | Aircraft code, IATA         |
| <code>model</code>         | <code>text</code>    | <code>not null</code> | Aircraft model              |
| <code>range</code>         | <code>integer</code> | <code>not null</code> | Maximal flying distance, km |

View definition:

```
SELECT ml.aircraft_code,
       ml.model ->> lang() AS model,
       ml.range
FROM   aircrafts_data ml;
```

### M.4.3. Table `bookings.aircrafts_data`

This is the base table for the `aircrafts` view. The `model` field of this table contains translations of aircraft models to different languages, in the JSONB format. In most cases, this table is not supposed to be used directly.

| Column                     | Type                 | Modifiers             | Description         |
|----------------------------|----------------------|-----------------------|---------------------|
| <code>aircraft_code</code> | <code>char(3)</code> | <code>not null</code> | Aircraft code, IATA |

```

model          | jsonb   | not null   | Aircraft model
range          | integer | not null   | Maximal flying distance, km

```

Indexes:

```

```

Check constraints:

```
CHECK (range > 0)
```

Referenced by:

```

TABLE "flights" FOREIGN KEY (aircraft_code)
REFERENCES aircrafts_data(aircraft_code)
TABLE "seats" FOREIGN KEY (aircraft_code)
REFERENCES aircrafts_data(aircraft_code) ON DELETE CASCADE

```

#### M.4.4. View bookings.airports

An airport is identified by a three-letter code (`airport_code`) and has a name (`airport_name`).

There is no separate entity for the city, but there is a city name (`city`) to identify the airports of the same city. The view also includes coordinates (`coordinates`) and the time zone (`timezone`).

The values of the `airport_name` and `city` fields are selected according to the chosen language. See [Section M.4.15](#) for details.

| Column                    | Type                 | Modifiers             | Description                                  |
|---------------------------|----------------------|-----------------------|----------------------------------------------|

```

### M.4.6. Table `bookings.boarding_passes`

At the time of check-in, which opens twenty-four hours before the scheduled departure, the passenger is issued a boarding pass. Like the flight segment, the boarding pass is identified by the ticket number and the flight number.

Boarding passes are assigned sequential numbers (`boarding_no`), in the order of check-ins for the flight (this number is unique only within the context of a particular flight). The boarding pass specifies the seat number (`seat_no`).

| Column                   | Type                    | Modifiers             | Description          |
|--------------------------|-------------------------|-----------------------|----------------------|
| <code>ticket_no</code>   | <code>char(13)</code>   | <code>not null</code> | Ticket number        |
| <code>flight_id</code>   | <code>integer</code>    | <code>not null</code> | Flight ID            |
| <code>boarding_no</code> | <code>integer</code>    | <code>not null</code> | Boarding pass number |
| <code>seat_no</code>     | <code>varchar(4)</code> | <code>not null</code> | Seat number          |

Indexes:

```

UNIQUE CONSTRAINT, btree (flight_id, boarding_no)
UNIQUE CONSTRAINT, btree (flight_id, seat_no)
```

Foreign-key constraints:

```
FOREIGN KEY (ticket_no, flight_id)
REFERENCES ticket_flights(ticket_no, flight_id)
```

### M.4.7. Table `bookings.bookings`

Passengers book tickets for themselves, and, possibly, for several other passengers, in advance (`book_date`, not earlier than one month before the flight). The booking is identified by its number (`book_ref`, a six-position combination of letters and digits).

The `total_amount` field stores the total cost of all tickets included into the booking, for all passengers.

| Column                    | Type                       | Modifiers             | Description        |
|---------------------------|----------------------------|-----------------------|--------------------|
| <code>book_ref</code>     | <code>char(6)</code>       | <code>not null</code> | Booking number     |
| <code>book_date</code>    | <code>timestampz</code>    | <code>not null</code> | Booking date       |
| <code>total_amount</code> | <code>numeric(10,2)</code> | <code>not null</code> | Total booking cost |

Indexes:

```
PRIMARY KEY, btree (book_ref)
```

Referenced by:

```
TABLE "tickets" FOREIGN KEY (book_ref) REFERENCES bookings(book_ref)
```

### M.4.8. Table `bookings.flights`

The natural key of the `bookings.flights` table consists of two fields — `flight_no` and `scheduled_departure`. To make foreign keys for this table more compact, a surrogate key is used as the primary key (`flight_id`).

A flight always connects two points — the airport of departure (`departure_airport`) and arrival (`arrival_airport`). There is no such entity as a “connecting flight”: if there are no non-stop flights from one airport to another, the ticket simply includes several required flight segments.

Each flight has a scheduled date and time of departure (`scheduled_departure`) and arrival (`scheduled_arrival`). The actual departure time (`actual_departure`) and arrival time (`actual_arrival`) can differ: the difference is usually not very big, but sometimes can be up to several hours if the flight is delayed.

**Flight status** (*status*) can take one of the following values:

Scheduled

The flight is available for booking. It happens one month before the planned departure date; before that time, there is no entry for this flight in the database.

On Time

The flight is open for check-in (in twenty-four hours before the scheduled departure) and is not delayed.

Delayed

The flight is open for check-in (in twenty-four hours before the scheduled departure) but is delayed.

Departed

The aircraft has already departed and is airborne.

Arrived

The aircraft has reached the point of destination.

Cancelled

The flight is canceled.

| Column              | Type        | Modifiers | Description              |
|---------------------|-------------|-----------|--------------------------|
| flight_id           | serial      | not null  | Flight ID                |
| flight_no           | char(6)     | not null  | Flight number            |
| scheduled_departure | timestampz  | not null  | Scheduled departure time |
| scheduled_arrival   | timestampz  | not null  | Scheduled arrival time   |
| departure_airport   | char(3)     | not null  | Airport of departure     |
| arrival_airport     | char(3)     | not null  | Airport of arrival       |
| status              | varchar(20) | not null  | Flight status            |
| aircraft_code       | char(3)     | not null  | Aircraft code, IATA      |
| actual_departure    | timestampz  |           | Actual departure time    |
| actual_arrival      | timestampz  |           | Actual arrival time      |

Indexes:

Referenced by:

TABLE "ticket\_flights" FOREIGN KEY (flight\_id)  
   REFERENCES flights(flight\_id)

### M.4.9. Table bookings.seats

Seats define the cabin configuration of each aircraft model. Each seat is defined by its number (`seat_no`) and has an assigned travel class (`fare_conditions`): Economy, Comfort or Business.

| Column                       | Type                     | Modifiers             | Description         |

```

Check constraints:

```
CHECK (fare_conditions IN ('Economy', 'Comfort', 'Business'))
```

Foreign-key constraints:

```
FOREIGN KEY (aircraft_code)
```

```
REFERENCES aircrafts(aircraft_code) ON DELETE CASCADE
```

### M.4.10. Table bookings.ticket\_flights

A flight segment connects a ticket with a flight and is identified by their numbers.

Each flight has its cost (`amount`) and travel class (`fare_conditions`).

| Column                       | Type                       | Modifiers             | Description   |
|------------------------------|----------------------------|-----------------------|---------------|
| <code>ticket_no</code>       | <code>char(13)</code>      | <code>not null</code> | Ticket number |
| <code>flight_id</code>       | <code>integer</code>       | <code>not null</code> | Flight ID     |
| <code>fare_conditions</code> | <code>varchar(10)</code>   | <code>not null</code> | Travel class  |
| <code>amount</code>          | <code>numeric(10,2)</code> | <code>not null</code> | Travel cost   |

Indexes:

```
PRIMARY KEY, btree (ticket_no, flight_id)
```

Check constraints:

```
CHECK (amount >= 0)
```

```
CHECK (fare_conditions IN ('Economy', 'Comfort', 'Business'))
```

Foreign-key constraints:

```
FOREIGN KEY (flight_id) REFERENCES flights(flight_id)
```

```
FOREIGN KEY (ticket_no) REFERENCES tickets(ticket_no)
```

Referenced by:

```
TABLE "boarding_passes" FOREIGN KEY (ticket_no, flight_id)
```

```
REFERENCES ticket_flights(ticket_no, flight_id)
```

### M.4.11. Table bookings.tickets

A ticket has a unique number (`ticket_no`) that consists of 13 digits.

The ticket includes a passenger ID (`passenger_id`) — the identity document number, — their first and last names (`passenger_name`), and contact information (`contact_data`).

Neither the passenger ID, nor the name is permanent (for example, one can change the last name or passport), so it is impossible to uniquely identify all tickets of a particular passenger.

| Column                      | Type                     | Modifiers             | Description    |
|-----------------------------|--------------------------|-----------------------|----------------|
| <code>ticket_no</code>      | <code>char(13)</code>    | <code>not null</code> | Ticket number  |
| <code>book_ref</code>       | <code>char(6)</code>     | <code>not null</code> | Booking number |
| <code>passenger_id</code>   | <code>varchar(20)</code> | <code>not null</code> | Passenger ID   |
| <code>passenger_name</code> | <code>text</code>        | <code>not null</code> | Passenger name |

```

contact_data | jsonb | Passenger contact information
Indexes:
PRIMARY KEY, btree (ticket_no)
Foreign-key constraints:

Referenced by:
TABLE "ticket_flights" FOREIGN KEY (ticket_no) REFERENCES tickets(ticket_no)

```

### M.4.12. View bookings.flights\_v

There is a `flights_v` view over the `flights` table that provides additional information:

- Details about the airport of departure — `departure_airport`, `departure_airport_name`, `departure_city`
- Details about the airport of arrival — `arrival_airport`, `arrival_airport_name`, `arrival_city`
- Local departure time — `scheduled_departure_local`, `actual_departure_local`
- Local arrival time — `scheduled_arrival_local`, `actual_arrival_local`
- Flight duration — `scheduled_duration`, `actual_duration`.

| Column                                 | Type                     | Description                                                       |
|----------------------------------------|--------------------------|-------------------------------------------------------------------|
| <code>flight_id</code>                 | <code>integer</code>     | Flight ID                                                         |
| <code>flight_no</code>                 | <code>char(6)</code>     | Flight number                                                     |
| <code>scheduled_departure</code>       | <code>timestamptz</code> | Scheduled departure time                                          |

### M.4.13. View bookings.routes

The `bookings.flights` table contains some redundancies, which you can use to single out route information (flight number, airports of departure and destination) that does not depend on the exact flight dates.

Such information is shown in the `routes` view.

| Column | Type | Description |
|--------|------|-------------|
|--------|------|-------------|

|                        |           |                                                 |
|------------------------|-----------|-------------------------------------------------|
| flight_no              | char(6)   | Flight number                                   |
| departure_airport      | char(3)   | Departure airport code                          |
| departure_airport_name | text      | Departure airport name                          |
| departure_city         | text      | City of departure                               |
| arrival_airport        | char(3)   | Arrival airport code                            |
| arrival_airport_name   | text      | Arrival airport name                            |
| arrival_city           | text      | City of arrival                                 |
| aircraft_code          | char(3)   | Aircraft code, IATA                             |
| duration               | interval  | Flight duration                                 |
| days_of_week           | integer[] | Days of the week on which flights are performed |

#### M.4.14. Function `bookings.now`

The demo database contains “snapshots” of data — similar to a backup copy of a real system captured at some point in time. For example, if a flight has the `Departed` status, it means that the aircraft had already departed and was airborne at the time of the backup copy.

The “snapshot” time is saved in the `bookings.now()` function. You can use this function in demo queries for cases where you would use the `now()` function in a real database.

In addition, the return value of this function determines the version of the demo database. The latest version available is of August 15, 2017.

#### M.4.15. Function `bookings.lang`

Some fields in the demo database are available in English and Russian. Translations to other languages are not provided, but are easy to add. The `bookings.lang` returns the value of the `bookings.lang` parameter, that is, the language in which these fields will be displayed.

This function is used in the `aircrafts` and `airports` views and is not intended to be used directly in queries.

### M.5. Usage

#### M.5.1. Schema `bookings`

The `bookings` schema contains all objects of the demo database. When you connect to the database, `search_path` configuration parameter is automatically set to `bookings, public`, so you do not need to specify the schema name explicitly.

However, for the `bookings.now` function, you always have to specify the schema to distinguish this function from the standard `now` function.

#### M.5.2. Translations

By default, values of several translatable fields are shown in Russian. These are `airport_name` and `city` of the `airports` view, as well as `model` of the `aircrafts` view.

You can choose to display these fields in another language (although only the English translation is provided in the demo database). To switch to English, set the `bookings.lang` parameter to `en`. It may be convenient to choose the language at the database level:

```
ALTER DATABASE demo SET bookings.lang = en;
```

You have to reconnect to the database for this command to take effect. For other methods of settings configuration parameters, see [Section 19.1](#).

In the examples below, the English language is selected for translatable fields.

### M.5.3. Sample Queries

To better understand the contents of the demo database, let's take a look at the results of several simple queries.

The results displayed below were received on a small database version (demo-small) of August 15, 2017. If the same queries return different data on your system, check your demo database version (using the `bookings.now` function). Some minor deviations may be caused by the difference between your local time and Moscow time, or your locale settings.

All flights are operated by several types of aircraft:

```
SELECT * FROM aircrafts;
```

| aircraft_code | model               | range |
|---------------|---------------------|-------|
| 773           | Boeing 777-300      | 11100 |
| 763           | Boeing 767-300      | 7900  |
| SU9           | Sukhoi SuperJet-100 | 3000  |
| 320           | Airbus A320-200     | 5700  |
| 321           | Airbus A321-200     | 5600  |
| 319           | Airbus A319-100     | 6700  |
| 733           | Boeing 737-300      | 4200  |
| CN1           | Cessna 208 Caravan  | 1200  |
| CR2           | Bombardier CRJ-200  | 2700  |

(9 rows)

For each aircraft type, a separate list of seats is supported. For example, in a small Cessna 208 Caravan, one can select the following seats:

```
SELECT  a.aircraft_code,
        a.model,
        s.seat_no,
        s.fare_conditions
FROM    aircrafts a
        JOIN seats s ON a.aircraft_code = s.aircraft_code
WHERE   a.model = 'Cessna 208 Caravan'
ORDER BY s.seat_no;
```

| aircraft_code | model              | seat_no | fare_conditions |
|---------------|--------------------|---------|-----------------|
| CN1           | Cessna 208 Caravan | 1A      | Economy         |
| CN1           | Cessna 208 Caravan | 1B      | Economy         |
| CN1           | Cessna 208 Caravan | 2A      | Economy         |
| CN1           | Cessna 208 Caravan | 2B      | Economy         |
| CN1           | Cessna 208 Caravan | 3A      | Economy         |
| CN1           | Cessna 208 Caravan | 3B      | Economy         |
| CN1           | Cessna 208 Caravan | 4A      | Economy         |
| CN1           | Cessna 208 Caravan | 4B      | Economy         |
| CN1           | Cessna 208 Caravan | 5A      | Economy         |
| CN1           | Cessna 208 Caravan | 5B      | Economy         |
| CN1           | Cessna 208 Caravan | 6A      | Economy         |
| CN1           | Cessna 208 Caravan | 6B      | Economy         |

(12 rows)

Bigger aircraft have more seats of various travel classes:

```
SELECT  s2.aircraft_code,
```

```

        string_agg (s2.fare_conditions || '(' || s2.num::text || ')',
                    ', ') as fare_conditions
FROM      (
        SELECT    s.aircraft_code, s.fare_conditions, count(*) as num
        FROM      seats s
        GROUP BY  s.aircraft_code, s.fare_conditions
        ORDER BY  s.aircraft_code, s.fare_conditions
        ) s2
GROUP BY  s2.aircraft_code
ORDER BY  s2.aircraft_code;

```

| aircraft_code | fare_conditions                            |
|---------------|--------------------------------------------|
| 319           | Business (20), Economy (96)                |
| 320           | Business (20), Economy (120)               |
| 321           | Business (28), Economy (142)               |
| 733           | Business (12), Economy (118)               |
| 763           | Business (30), Economy (192)               |
| 773           | Business (30), Comfort (48), Economy (324) |
| CN1           | Economy (12)                               |
| CR2           | Economy (50)                               |
| SU9           | Business (12), Economy (85)                |

(9 rows)

The demo database contains the list of airports of almost all major Russian cities. Most cities have only one airport. The exceptions are:

```

SELECT    a.airport_code as code,
          a.airport_name,
          a.city,
          a.coordinates
FROM      airports a
WHERE     a.city IN (
          SELECT    aa.city
          FROM      airports aa
          GROUP BY  aa.city
          HAVING    COUNT(*) > 1
          )
ORDER BY  a.city, a.airport_code;

```

| code | airport_name           | city      | coordinates                          |
|------|------------------------|-----------|--------------------------------------|
| DME  | Domodedovo             | Moscow    | (37.9062995910645, 55.4087982177734) |
|      | International Airport  |           |                                      |
| SVO  | Sheremetyevo           | Moscow    | (37.4146, 55.972599)                 |
|      | International Airport  |           |                                      |
| VKO  | Vnukovo                | Moscow    | (37.2615013123, 55.5914993286)       |
|      | International Airport  |           |                                      |
| ULV  | Ulyanovsk              | Ulyanovsk | (48.2266998291, 54.2682991028)       |
|      | Baratayevka Airport    |           |                                      |
| ULY  | Ulyanovsk East Airport | Ulyanovsk | (48.8027000427246, 54.4010009765625) |

(5 rows)

To learn about your flying options from one point to another, it is convenient to use the `routes` materialized view that aggregates information on all flights. For example, here are the destinations where you can get from Volgograd on specific days of the week, with flight duration:

```
SELECT r.arrival_city as city,
       r.arrival_airport as code,
       r.arrival_airport_name as airport_name,
       r.days_of_week,
       r.duration
FROM   routes r
WHERE  r.departure_city = 'Volgograd';
```

| city        | code | airport_name                       | days_of_week    | duration |
|-------------|------|------------------------------------|-----------------|----------|
| Moscow      | SVO  | Sheremetyevo International Airport | {1,2,3,4,5,6,7} | 01:15:00 |
| Chelyabinsk | CEK  | Chelyabinsk Balandino Airport      | {1,2,3,4,5,6,7} | 01:50:00 |
| Rostov      | ROV  | Rostov-on-Don Airport              | {1,2,3,4,5,6,7} | 00:30:00 |
| Moscow      | VKO  | Vnukovo International Airport      | {1,2,3,4,5,6,7} | 01:10:00 |
| Cheboksary  | CSY  | Cheboksary Airport                 | {1,2,3,4,5,6,7} | 02:45:00 |
| Tomsk       | TOF  | Bogashevo Airport                  | {1}             | 03:50:00 |

(6 rows)

The database was formed at the moment returned by the `bookings.now()` function:

```
SELECT bookings.now() as now;
```

| now                    |
|------------------------|
| 2017-08-15 18:00:00+03 |

In relation to this moment, all flights are classified as past and future flights:

```
SELECT status,
       count(*) as count,
       min(scheduled_departure) as min_scheduled_departure,
       max(scheduled_departure) as max_scheduled_departure
FROM   flights
GROUP BY status
ORDER BY min_scheduled_departure;
```

| status    | count | min_scheduled_departure | max_scheduled_departure |
|-----------|-------|-------------------------|-------------------------|
| Arrived   | 16707 | 2017-07-16 01:50:00+03  | 2017-08-15 17:25:00+03  |
| Cancelled | 414   | 2017-07-19 11:35:00+03  | 2017-09-14 20:55:00+03  |
| Departed  | 58    | 2017-08-15 09:55:00+03  | 2017-08-15 17:50:00+03  |
| Delayed   | 41    | 2017-08-15 15:15:00+03  | 2017-08-16 17:25:00+03  |
| On Time   | 518   | 2017-08-15 17:55:00+03  | 2017-08-16 18:00:00+03  |
| Scheduled | 15383 | 2017-08-16 18:05:00+03  | 2017-09-14 20:40:00+03  |

(6 rows)

Let's find the next flight from Yekaterinburg to Moscow. The `flight` table is not very convenient for such queries, as it does not include information on the cities of departure and arrival. That is why we will use the `flights_v` view:

```
\x
SELECT f.*
FROM   flights_v f
WHERE  f.departure_city = 'Yekaterinburg'
AND    f.arrival_city = 'Moscow'
```

```
AND      f.scheduled_departure > bookings.now()
ORDER BY f.scheduled_departure
LIMIT   1;
```

```
-[ RECORD 1 ]-----+-----
flight_id      | 10927
flight_no      | PG0226
scheduled_departure | 2017-08-16 08:10:00+03
scheduled_departure_local | 2017-08-16 10:10:00
scheduled_arrival | 2017-08-16 09:55:00+03
scheduled_arrival_local | 2017-08-16 09:55:00
scheduled_duration | 01:45:00
departure_airport | SVX
departure_airport_name | Koltsovo Airport
departure_city | Yekaterinburg
arrival_airport | SVO
arrival_airport_name | Sheremetyevo International Airport
arrival_city | Moscow
status | On Time
aircraft_code | 773
actual_departure |
actual_departure_local |
actual_arrival |
actual_arrival_local |
actual_duration |
```

Note that the `flights_v` view shows both Moscow time and local time at the airports of departure and arrival.

## M.5.4. Bookings

Each booking can include several tickets, one for each passenger. The ticket, in its turn, can include several flight segments. The complete information about the booking is stored in three tables: `bookings`, `tickets`, and `ticket_flights`.

Let's find several most expensive bookings:

```
SELECT  *
FROM    bookings
ORDER BY total_amount desc
LIMIT   10;
```

| book_ref | book_date              | total_amount |
|----------|------------------------|--------------|
| 3B54BB   | 2017-07-05 17:08:00+03 | 1204500.00   |
| 3AC131   | 2017-07-31 01:06:00+03 | 1087100.00   |
| 65A6EA   | 2017-07-03 06:28:00+03 | 1065600.00   |
| D7E9AA   | 2017-08-08 05:29:00+03 | 1062800.00   |
| EF479E   | 2017-08-02 15:58:00+03 | 1035100.00   |
| 521C53   | 2017-07-08 09:25:00+03 | 985500.00    |
| 514CA6   | 2017-07-27 05:07:00+03 | 955000.00    |
| D70BD9   | 2017-07-05 12:47:00+03 | 947500.00    |
| EC7EDA   | 2017-07-02 16:13:00+03 | 946800.00    |
| 8E4370   | 2017-07-28 02:04:00+03 | 945700.00    |

(10 rows)

Let's take a look at the tickets included into the booking with code 521C53:

```
SELECT ticket_no,
       passenger_id,
       passenger_name
FROM   tickets
WHERE  book_ref = '521C53';
```

| ticket_no     | passenger_id | passenger_name     |
|---------------|--------------|--------------------|
| 0005432661914 | 8234 547529  | IVAN IVANOV        |
| 0005432661915 | 2034 201228  | ANTONINA KUZNECOVA |

(2 rows)

If we would like to know, which flight segments are included into Antonina Kuznecova's ticket, we can use the following query:

```
SELECT  to_char(f.scheduled_departure, 'DD.MM.YYYY') AS when,
        f.departure_city || ' (' || f.departure_airport || ')' AS departure,
        f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
        tf.fare_conditions AS class,
        tf.amount
FROM    ticket_flights tf
        JOIN flights_v f ON tf.flight_id = f.flight_id
WHERE   tf.ticket_no = '0005432661915'
ORDER BY f.scheduled_departure;
```

| when       | departure             | arrival               | class    | amount    |
|------------|-----------------------|-----------------------|----------|-----------|
| 29.07.2017 | Moscow (SVO)          | Anadyr (DYR)          | Business | 185300.00 |
| 02.08.2017 | Anadyr (DYR)          | Khabarovsk (KHV)      | Business | 92200.00  |
| 03.08.2017 | Khabarovsk (KHV)      | Blagoveshchensk (BQS) | Business | 18000.00  |
| 08.08.2017 | Blagoveshchensk (BQS) | Khabarovsk (KHV)      | Business | 18000.00  |
| 12.08.2017 | Khabarovsk (KHV)      | Anadyr (DYR)          | Economy  | 30700.00  |
| 17.08.2017 | Anadyr (DYR)          | Moscow (SVO)          | Business | 185300.00 |

(6 rows)

As we can see, high booking cost is explained by multiple long-haul flights in business class.

Some of the flight segments in this ticket have earlier dates than the `bookings.now()` return value: it means that these flights had already happened. The last flight had not happened yet at the time of the database creation. After the check-in, a boarding pass with the allocated seat number is issued. We can check the exact seats occupied by Antonina (note the outer left join with table `boarding_passes`):

```
SELECT  to_char(f.scheduled_departure, 'DD.MM.YYYY') AS when,
        f.departure_city || ' (' || f.departure_airport || ')' AS departure,
        f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
        f.status,
        bp.seat_no
FROM    ticket_flights tf
        JOIN flights_v f ON tf.flight_id = f.flight_id
        LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id
        AND tf.ticket_no = bp.ticket_no
WHERE   tf.ticket_no = '0005432661915'
ORDER BY f.scheduled_departure;
```

| when | departure | arrival | status | seat_no |
|------|-----------|---------|--------|---------|
|------|-----------|---------|--------|---------|

```

29.07.2017 | Moscow (SVO)          | Anadyr (DYR)          | Arrived   | 5C
02.08.2017 | Anadyr (DYR)          | Khabarovsk (KHV)      | Arrived   | 1D
03.08.2017 | Khabarovsk (KHV)      | Blagoveshchensk (BQS) | Arrived   | 2C
08.08.2017 | Blagoveshchensk (BQS) | Khabarovsk (KHV)      | Arrived   | 2D
12.08.2017 | Khabarovsk (KHV)      | Anadyr (DYR)          | Arrived   | 20B
17.08.2017 | Anadyr (DYR)          | Moscow (SVO)          | Scheduled |
(6 rows)

```

### M.5.5. New Booking

Let's try to send Aleksandr Radishchev from Saint Petersburg to Moscow — the route that made him famous. Naturally, he will travel for free and in business class. We have already found a flight for tomorrow, and a return flight a week later.

```

BEGIN;

INSERT INTO bookings (book_ref, book_date, total_amount)
VALUES      ('_QWE12', bookings.now(), 0);

INSERT INTO tickets (ticket_no, book_ref, passenger_id, passenger_name)
VALUES      ('_0000000000001', '_QWE12', '1749 051790', 'ALEKSANDR RADISHCHEV');

INSERT INTO ticket_flights (ticket_no, flight_id, fare_conditions, amount)
VALUES      ('_0000000000001', 8525, 'Business', 0),
            ('_0000000000001', 4967, 'Business', 0);

COMMIT;

```

To avoid conflicts with the range of values present in the database, identifiers are started with an underscore.

We will check in Aleksandr for tomorrow's flight right away:

```

INSERT INTO boarding_passes (ticket_no, flight_id, boarding_no, seat_no)
VALUES      ('_0000000000001', 8525, 1, '1A');

```

Now let's check the booking information:

```

SELECT      b.book_ref,
            t.ticket_no,
            t.passenger_id,
            t.passenger_name,
            tf.fare_conditions,
            tf.amount,
            f.scheduled_departure_local,
            f.scheduled_arrival_local,
            f.departure_city || ' (' || f.departure_airport || ')' AS departure,
            f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
            f.status,
            bp.seat_no
FROM        bookings b
            JOIN tickets t ON b.book_ref = t.book_ref
            JOIN ticket_flights tf ON tf.ticket_no = t.ticket_no
            JOIN flights_v f ON tf.flight_id = f.flight_id
            LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id
                                AND tf.ticket_no = bp.ticket_no
WHERE       b.book_ref = '_QWE12'

```

ORDER BY t.ticket\_no, f.scheduled\_departure;

```

# Appendix N. Acronyms

This is a list of acronyms commonly used in the Postgres Pro documentation and in discussions about Postgres Pro.

ANSI

*American National Standards Institute*

API

*Application Programming Interface*

ASCII

*American Standard Code for Information Interchange*

BKI

Backend Interface

CA

*Certificate Authority*

CIDR

*Classless Inter-Domain Routing*

CPAN

*Comprehensive Perl Archive Network*

CRL

*Certificate Revocation List*

CSV

*Comma Separated Values*

CTE

Common Table Expression

CVE

*Common Vulnerabilities and Exposures*

DBA

*Database Administrator*

DBI

*Database Interface (Perl)*

DBMS

*Database Management System*

DDL

*Data Definition Language*, SQL commands such as `CREATE TABLE`, `ALTER USER`

DML

*Data Manipulation Language*, SQL commands such as `INSERT`, `UPDATE`, `DELETE`

DST

*Daylight Saving Time*

ECPG

Embedded C for Postgres Pro

ESQL

*Embedded SQL*

FAQ

*Frequently Asked Questions*

FSM

Free Space Map

GEQO

Genetic Query Optimizer

GIN

Generalized Inverted Index

GiST

Generalized Search Tree

Git

*Git*

GMT

*Greenwich Mean Time*

GSSAPI

*Generic Security Services Application Programming Interface*

GUC

*Grand Unified Configuration*, the Postgres Pro subsystem that handles server configuration

HBA

Host-Based Authentication

HOT

Heap-Only Tuples

IEC

*International Electrotechnical Commission*

IEEE

*Institute of Electrical and Electronics Engineers*

IPC

*Inter-Process Communication*

ISO

*International Organization for Standardization*

ISSN

*International Standard Serial Number*

JDBC

*Java Database Connectivity*

JIT

*Just-in-Time compilation*

JSON

*JavaScript Object Notation*

LDAP

*Lightweight Directory Access Protocol*

LSN

Log Sequence Number, see [pg\\_lsn](#) and [WAL Internals](#).

MITM

*Man-in-the-middle attack*

MSVC

*Microsoft Visual C*

MVCC

*Multi-Version Concurrency Control*

NLS

*National Language Support*

ODBC

*Open Database Connectivity*

OID

*Object Identifier*

OLAP

*Online Analytical Processing*

OLTP

*Online Transaction Processing*

ORDBMS

*Object-Relational Database Management System*

PAM

*Pluggable Authentication Modules*

PGSQL

*Postgres Pro*

PGXS

*Postgres Pro Extension System*

PID

*Process Identifier*

PITR

*Point-In-Time Recovery (Continuous Archiving)*

PL

*Procedural Languages (server-side)*

POSIX

*Portable Operating System Interface*

RDBMS

*Relational Database Management System*

RFC

*Request For Comments*

SGML

*Standard Generalized Markup Language*

SNI

*Server Name Indication, RFC 6066*

SPI

*Server Programming Interface*

SP-GiST

*Space-Partitioned Generalized Search Tree*

SQL

*Structured Query Language*

SRF

*Set-Returning Function*

SSH

*Secure Shell*

SSL

*Secure Sockets Layer*

SSPI

*Security Support Provider Interface*

SYSV

*Unix System V*

TCP/IP

*Transmission Control Protocol (TCP) / Internet Protocol (IP)*

TID

*Tuple Identifier*

TLS

*Transport Layer Security*

TOAST

*The Oversized-Attribute Storage Technique*

TPC

*Transaction Processing Performance Council*

URL

*Uniform Resource Locator*

UTC

*Coordinated Universal Time*

UTF

*Unicode Transformation Format*

UTF8

*Eight-Bit Unicode Transformation Format*

UUID

*Universally Unique Identifier*

WAL

*Write-Ahead Log*

XID

*Transaction Identifier*

XML

*Extensible Markup Language*

---

# Appendix O. Glossary

This is a list of terms and their meaning in the context of PostgreSQL and relational database systems in general.

|                              |        |                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACID                         |        | <a href="#">Atomicity</a> , <a href="#">Consistency</a> , <a href="#">Isolation</a> , and <a href="#">Durability</a> . This set of properties of database transactions is intended to guarantee validity in concurrent operation and even in event of errors, power failures, etc.                                                                                                                    |
| Aggregate function (routine) |        | <p>A <a href="#">function</a> that combines (<i>aggregates</i>) multiple input values, for example by counting, averaging or adding, yielding a single output value.</p> <p>For more information, see <a href="#">Section 9.21</a>.</p> <p>See Also <a href="#">Window function (routine)</a>.</p>                                                                                                    |
| Analytic function            |        | See <a href="#">Window function (routine)</a> .                                                                                                                                                                                                                                                                                                                                                       |
| Analyze (operation)          |        | <p>The process of collecting statistics from data in <a href="#">tables</a> and other <a href="#">relations</a> to help the <a href="#">query planner</a> to make decisions about how to execute <a href="#">queries</a>.</p> <p>(Don't confuse this term with the <code>ANALYZE</code> option to the <a href="#">EXPLAIN</a> command.)</p> <p>For more information, see <a href="#">ANALYZE</a>.</p> |
| Atomic                       |        | <p>In reference to a <a href="#">datum</a>: the fact that its value cannot be broken down into smaller components.</p> <p>In reference to a <a href="#">database transaction</a>: see <a href="#">atomicity</a>.</p>                                                                                                                                                                                  |
| Atomicity                    |        | The property of a <a href="#">transaction</a> that either all its operations complete as a single unit or none do. In addition, if a system failure occurs during the execution of a transaction, no partial results are visible after recovery. This is one of the ACID properties.                                                                                                                  |
| Attribute                    |        | An element with a certain name and data type found within a <a href="#">tuple</a> .                                                                                                                                                                                                                                                                                                                   |
| Autovacuum (process)         |        | <p>A set of background processes that routinely perform <a href="#">vacuum</a> and <a href="#">analyze</a> operations.</p> <p>For more information, see <a href="#">Section 24.1.6</a>.</p>                                                                                                                                                                                                           |
| Backend (process)            |        | <p>Process of an <a href="#">instance</a> which acts on behalf of a <a href="#">client session</a> and handles its requests.</p> <p>(Don't confuse this term with the similar terms <a href="#">Background Worker</a> or <a href="#">Background Writer</a>).</p>                                                                                                                                      |
| Background (process)         | worker | <p>Process within an <a href="#">instance</a>, which runs system- or user-supplied code. Serves as infrastructure for several features in PostgreSQL, such as <a href="#">logical replication</a> and <a href="#">parallel queries</a>. In addition, <a href="#">Extensions</a> can add custom background worker processes.</p> <p>For more information, see <a href="#">Chapter 50</a>.</p>          |
| Background (process)         | writer | <p>A process that writes dirty <a href="#">data pages</a> from <a href="#">shared memory</a> to the file system. It wakes up periodically, but works only for a short period in order to distribute its expensive I/O activity over time to avoid generating larger I/O peaks which could block other processes.</p> <p>For more information, see <a href="#">Section 19.4.5</a>.</p>                 |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Base Backup            | <p>A binary copy of all <i>database cluster</i> files. It is generated by the tool <i>pg_basebackup</i>. In combination with WAL files it can be used as the starting point for recovery, log shipping, or streaming replication.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Bloat                  | <p>Space in data pages which does not contain current row versions, such as unused (free) space or outdated row versions.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Cast                   | <p>A conversion of a <i>datum</i> from its current data type to another data type.</p> <p>For more information, see <i>CREATE CAST</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Catalog                | <p>The SQL standard uses this term to indicate what is called a <i>database</i> in PostgreSQL's terminology.</p> <p>(Don't confuse this term with <i>system catalog</i>).</p> <p>For more information, see <i>Section 22.1</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Check constraint       | <p>A type of <i>constraint</i> defined on a <i>relation</i> which restricts the values allowed in one or more <i>attributes</i>. The check constraint can make reference to any attribute of the same row in the relation, but cannot reference other rows of the same relation or other relations.</p> <p>For more information, see <i>Section 5.4</i>.</p>                                                                                                                                                                                                                                                                                                                                                   |
| Checkpoint             | <p>A point in the <i>WAL</i> sequence at which it is guaranteed that the heap and index data files have been updated with all information from <i>shared memory</i> modified before that checkpoint; a <i>checkpoint record</i> is written and flushed to WAL to mark that point.</p> <p>A checkpoint is also the act of carrying out all the actions that are necessary to reach a checkpoint as defined above. This process is initiated when pre-defined conditions are met, such as a specified amount of time has passed, or a certain volume of records has been written; or it can be invoked by the user with the command <i>CHECKPOINT</i>.</p> <p>For more information, see <i>Section 29.5</i>.</p> |
| Checkpointer (process) | <p>A specialized process responsible for executing checkpoints.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Class (archaic)        | <p>See <i>Relation</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Client (process)       | <p>Any process, possibly remote, that establishes a <i>session</i> by <i>connecting</i> to an <i>instance</i> to interact with a <i>database</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Column                 | <p>An <i>attribute</i> found in a <i>table</i> or <i>view</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Commit                 | <p>The act of finalizing a <i>transaction</i> within the <i>database</i>, which makes it visible to other transactions and assures its <i>durability</i>.</p> <p>For more information, see <i>COMMIT</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Concurrency            | <p>The concept that multiple independent operations happen within the <i>database</i> at the same time. In PostgreSQL, concurrency is controlled by the <i>multiversion concurrency control</i> mechanism.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Connection             | <p>An established line of communication between a client process and a <i>back-end</i> process, usually over a network, supporting a <i>session</i>. This term is sometimes used as a synonym for session.</p> <p>For more information, see <i>Section 19.3</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Consistency      | <p>The property that the data in the <a href="#">database</a> is always in compliance with <a href="#">integrity constraints</a>. Transactions may be allowed to violate some of the constraints transiently before it commits, but if such violations are not resolved by the time it commits, such a transaction is automatically <a href="#">rolled back</a>. This is one of the ACID properties.</p>                                                                                                                                         |
| Constraint       | <p>A restriction on the values of data allowed within a <a href="#">table</a>, or in attributes of a <a href="#">domain</a>.</p> <p>For more information, see <a href="#">Section 5.4</a>.</p>                                                                                                                                                                                                                                                                                                                                                   |
| Data area        | <p>See <a href="#">Data directory</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Database         | <p>A named collection of <a href="#">local SQL objects</a>.</p> <p>For more information, see <a href="#">Section 22.1</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Database cluster | <p>A collection of databases and global SQL objects, and their common static and dynamic metadata. Sometimes referred to as a <i>cluster</i>.</p> <p>In PostgreSQL, the term <i>cluster</i> is also sometimes used to refer to an instance. (Don't confuse this term with the SQL command <code>CLUSTER</code>.)</p>                                                                                                                                                                                                                             |
| Database server  | <p>See <a href="#">Instance</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Data directory   | <p>The base directory on the file system of a <a href="#">server</a> that contains all data files and subdirectories associated with a <a href="#">database cluster</a> (with the exception of <a href="#">tablespaces</a>, and optionally <a href="#">WAL</a>). The environment variable <code>PGDATA</code> is commonly used to refer to the data directory.</p> <p>A <a href="#">cluster</a>'s storage space comprises the data directory plus any additional tablespaces.</p> <p>For more information, see <a href="#">Section 70.1</a>.</p> |
| Data page        | <p>The basic structure used to store relation data. All pages are of the same size. Data pages are typically stored on disk, each in a specific file, and can be read to <a href="#">shared buffers</a> where they can be modified, becoming <i>dirty</i>. They become clean when written to disk. New pages, which initially exist in memory only, are also dirty until written.</p>                                                                                                                                                            |
| Datum            | <p>The internal representation of one value of an SQL data type.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Delete           | <p>An SQL command which removes <a href="#">rows</a> from a given <a href="#">table</a> or <a href="#">relation</a>.</p> <p>For more information, see <a href="#">DELETE</a>.</p>                                                                                                                                                                                                                                                                                                                                                                |
| Durability       | <p>The assurance that once a <a href="#">transaction</a> has been <a href="#">committed</a>, the changes remain even after a system failure or crash. This is one of the ACID properties.</p>                                                                                                                                                                                                                                                                                                                                                    |
| Extension        | <p>A software add-on package that can be installed on an <a href="#">instance</a> to get extra features.</p> <p>For more information, see <a href="#">Section 40.17</a>.</p>                                                                                                                                                                                                                                                                                                                                                                     |
| File segment     | <p>A physical file which stores data for a given <a href="#">relation</a>. File segments are limited in size by a configuration value (typically 1 gigabyte), so if a relation exceeds that size, it is split into multiple segments.</p> <p>For more information, see <a href="#">Section 70.1</a>.</p> <p>(Don't confuse this term with the similar term <a href="#">WAL segment</a>).</p>                                                                                                                                                     |

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Foreign data wrapper     | <p>A means of representing data that is not contained in the local <i>database</i> so that it appears as if were in local <i>table(s)</i>. With a foreign data wrapper it is possible to define a <i>foreign server</i> and <i>foreign tables</i>.</p> <p>For more information, see <a href="#">CREATE FOREIGN DATA WRAPPER</a>.</p>                                                                                                                              |
| Foreign key              | <p>A type of <i>constraint</i> defined on one or more <i>columns</i> in a <i>table</i> which requires the value(s) in those <i>columns</i> to identify zero or one <i>row</i> in another (or, infrequently, the same) <i>table</i>.</p>                                                                                                                                                                                                                           |
| Foreign server           | <p>A named collection of <i>foreign tables</i> which all use the same <i>foreign data wrapper</i> and have other configuration values in common.</p> <p>For more information, see <a href="#">CREATE SERVER</a>.</p>                                                                                                                                                                                                                                              |
| Foreign table (relation) | <p>A <i>relation</i> which appears to have <i>rows</i> and <i>columns</i> similar to a regular <i>table</i>, but will forward requests for data through its <i>foreign data wrapper</i>, which will return <i>result sets</i> structured according to the definition of the <i>foreign table</i>.</p> <p>For more information, see <a href="#">CREATE FOREIGN TABLE</a>.</p>                                                                                      |
| Fork                     | <p>Each of the separate segmented file sets in which a relation is stored. The <i>main fork</i> is where the actual data resides. There also exist two secondary forks for metadata: the <i>free space map</i> and the <i>visibility map</i>. <i>Unlogged relations</i> also have an <i>init fork</i>.</p>                                                                                                                                                        |
| Free space map (fork)    | <p>A storage structure that keeps metadata about each data page of a table's main fork. The free space map entry for each page stores the amount of free space that's available for future tuples, and is structured to be efficiently searched for available space for a new tuple of a given size.</p> <p>For more information, see <a href="#">Section 70.3</a>.</p>                                                                                           |
| Function (routine)       | <p>A type of routine that receives zero or more arguments, returns zero or more output values, and is constrained to run within one transaction. Functions are invoked as part of a query, for example via <code>SELECT</code>. Certain functions can return <i>sets</i>; those are called <i>set-returning functions</i>.</p> <p>Functions can also be used for <i>triggers</i> to invoke.</p> <p>For more information, see <a href="#">CREATE FUNCTION</a>.</p> |
| GMT                      | <p>See <a href="#">UTC</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Grant                    | <p>An SQL command that is used to allow a <i>user</i> or <i>role</i> to access specific objects within the <i>database</i>.</p> <p>For more information, see <a href="#">GRANT</a>.</p>                                                                                                                                                                                                                                                                           |
| Heap                     | <p>Contains the values of <i>row</i> attributes (i.e., the data) for a <i>relation</i>. The heap is realized within one or more <i>file segments</i> in the relation's <i>main fork</i>.</p>                                                                                                                                                                                                                                                                      |
| Host                     | <p>A computer that communicates with other computers over a network. This is sometimes used as a synonym for <i>server</i>. It is also used to refer to a computer where <i>client processes</i> run.</p>                                                                                                                                                                                                                                                         |
| Index (relation)         | <p>A <i>relation</i> that contains data derived from a <i>table</i> or <i>materialized view</i>. Its internal structure supports fast retrieval of and access to the original data.</p> <p>For more information, see <a href="#">CREATE INDEX</a>.</p>                                                                                                                                                                                                            |

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Insert                       | <p>An SQL command used to add new data into a <a href="#">table</a>.</p> <p>For more information, see <a href="#">INSERT</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Instance                     | <p>A group of backend and auxiliary processes that communicate using a common shared memory area. One <a href="#">postmaster process</a> manages the instance; one instance manages exactly one <a href="#">database cluster</a> with all its databases. Many instances can run on the same <a href="#">server</a> as long as their TCP ports do not conflict.</p> <p>The instance handles all key features of a DBMS: read and write access to files and shared memory, assurance of the ACID properties, <a href="#">connections</a> to <a href="#">client processes</a>, privilege verification, crash recovery, replication, etc.</p> |
| Isolation                    | <p>The property that the effects of a transaction are not visible to <a href="#">concurrent transactions</a> before it commits. This is one of the ACID properties.</p> <p>For more information, see <a href="#">Section 13.2</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                    |
| Join                         | <p>An operation and SQL keyword used in <a href="#">queries</a> for combining data from multiple <a href="#">relations</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Key                          | <p>A means of identifying a <a href="#">row</a> within a <a href="#">table</a> or other <a href="#">relation</a> by values contained within one or more <a href="#">attributes</a> in that relation.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Lock                         | <p>A mechanism that allows a process to limit or prevent simultaneous access to a resource.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Log file                     | <p>Log files contain human-readable text lines about events. Examples include login failures, long-running queries, etc.</p> <p>For more information, see <a href="#">Section 24.3</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Logged                       | <p>A <a href="#">table</a> is considered <a href="#">logged</a> if changes to it are sent to the <a href="#">WAL</a>. By default, all regular tables are logged. A table can be specified as <a href="#">unlogged</a> either at creation time or via the <code>ALTER TABLE</code> command.</p>                                                                                                                                                                                                                                                                                                                                            |
| Logger (process)             | <p>If activated, the process writes information about database events into the current <a href="#">log file</a>. When reaching certain time- or volume-dependent criteria, a new log file is created. Also called <i>syslogger</i>.</p> <p>For more information, see <a href="#">Section 19.8</a>.</p>                                                                                                                                                                                                                                                                                                                                    |
| Log record                   | <p>Archaic term for a <a href="#">WAL record</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Master (server)              | <p>See <a href="#">Primary (server)</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Materialized                 | <p>The property that some information has been pre-computed and stored for later use, rather than computing it on-the-fly.</p> <p>This term is used in <a href="#">materialized view</a>, to mean that the data derived from the view's query is stored on disk separately from the sources of that data.</p> <p>This term is also used to refer to some multi-step queries to mean that the data resulting from executing a given step is stored in memory (with the possibility of spilling to disk), so that it can be read multiple times by another step.</p>                                                                        |
| Materialized view (relation) | <p>A <a href="#">relation</a> that is defined by a <code>SELECT</code> statement (just like a <a href="#">view</a>), but stores data in the same way that a <a href="#">table</a> does. It cannot be modified via <code>INSERT</code>, <code>UPDATE</code>, or <code>DELETE</code> operations.</p>                                                                                                                                                                                                                                                                                                                                        |

|                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                          | For more information, see <a href="#">CREATE MATERIALIZED VIEW</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Multi-version concurrency control (MVCC) | A mechanism designed to allow several <a href="#">transactions</a> to be reading and writing the same rows without one process causing other processes to stall. In PostgreSQL, MVCC is implemented by creating copies ( <i>versions</i> ) of <a href="#">tuples</a> as they are modified; after transactions that can see the old versions terminate, those old versions need to be removed.                                                                                                                                                                                                                                                                                                         |
| Null                                     | A concept of non-existence that is a central tenet of relational database theory. It represents the absence of a definite value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Optimizer                                | See <a href="#">Query planner</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Parallel query                           | The ability to handle parts of executing a <a href="#">query</a> to take advantage of parallel processes on servers with multiple CPUs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Partition                                | One of several disjoint (not overlapping) subsets of a larger set.<br><br>In reference to a <a href="#">partitioned table</a> : One of the tables that each contain part of the data of the partitioned table, which is said to be the <i>parent</i> . The partition is itself a table, so it can also be queried directly; at the same time, a partition can sometimes be a partitioned table, allowing hierarchies to be created.<br><br>In reference to a <a href="#">window function</a> in a <a href="#">query</a> , a partition is a user-defined criterion that identifies which neighboring <a href="#">rows</a> of the <a href="#">query's result set</a> can be considered by the function. |
| Partitioned table (relation)             | A <a href="#">relation</a> that is in semantic terms the same as a <a href="#">table</a> , but whose storage is distributed across several <a href="#">partitions</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Postmaster (process)                     | The very first process of an <a href="#">instance</a> . It starts and manages the other auxiliary processes and creates <a href="#">backend processes</a> on demand.<br><br>For more information, see <a href="#">Section 18.3</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Primary key                              | A special case of a <a href="#">unique constraint</a> defined on a <a href="#">table</a> or other <a href="#">relation</a> that also guarantees that all of the <a href="#">attributes</a> within the <a href="#">primary key</a> do not have <a href="#">null</a> values. As the name implies, there can be only one primary key per table, though it is possible to have multiple unique constraints that also have no null-capable attributes.                                                                                                                                                                                                                                                     |
| Primary (server)                         | When two or more <a href="#">databases</a> are linked via <a href="#">replication</a> , the <a href="#">server</a> that is considered the authoritative source of information is called the <i>primary</i> , also known as a <i>master</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Procedure (routine)                      | A type of routine. Their distinctive qualities are that they do not return values, and that they are allowed to make transactional statements such as COMMIT and ROLLBACK. They are invoked via the CALL command.<br><br>For more information, see <a href="#">CREATE PROCEDURE</a> .                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Query                                    | A request sent by a client to a <a href="#">backend</a> , usually to return results or to modify data on the database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Query planner                            | The part of PostgreSQL that is devoted to determining ( <i>planning</i> ) the most efficient way to execute <a href="#">queries</a> . Also known as <i>query optimizer</i> , <i>optimizer</i> , or simply <i>planner</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Record                                   | See <a href="#">Tuple</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Recycling             | See <a href="#">WAL file</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Referential integrity | A means of restricting data in one <a href="#">relation</a> by a <a href="#">foreign key</a> so that it must have matching data in another <a href="#">relation</a> .                                                                                                                                                                                                                                                                                                                                                                                                   |
| Relation              | <p>The generic term for all objects in a <a href="#">database</a> that have a name and a list of <a href="#">attributes</a> defined in a specific order. <a href="#">Tables</a>, <a href="#">sequences</a>, <a href="#">views</a>, <a href="#">foreign tables</a>, <a href="#">materialized views</a>, composite types, and <a href="#">indexes</a> are all relations.</p> <p>More generically, a relation is a set of tuples; for example, the result of a query is also a relation.</p> <p>In PostgreSQL, <i>Class</i> is an archaic synonym for <i>relation</i>.</p> |
| Replica (server)      | A <a href="#">database</a> that is paired with a <a href="#">primary</a> database and is maintaining a copy of some or all of the primary database's data. The foremost reasons for doing this are to allow for greater access to that data, and to maintain availability of the data in the event that the <a href="#">primary</a> becomes unavailable.                                                                                                                                                                                                                |
| Replication           | The act of reproducing data on one <a href="#">server</a> onto another server called a <a href="#">replica</a> . This can take the form of <i>physical replication</i> , where all file changes from one server are copied verbatim, or <i>logical replication</i> where a defined subset of data changes are conveyed using a higher-level representation.                                                                                                                                                                                                             |
| Result set            | <p>A <a href="#">relation</a> transmitted from a <a href="#">backend process</a> to a <a href="#">client</a> upon the completion of an SQL command, usually a <code>SELECT</code> but it can be an <code>INSERT</code>, <code>UPDATE</code>, or <code>DELETE</code> command if the <code>RETURNING</code> clause is specified.</p> <p>The fact that a result set is a relation means that a query can be used in the definition of another query, becoming a <i>subquery</i>.</p>                                                                                       |
| Revoke                | <p>A command to prevent access to a named set of <a href="#">database</a> objects for a named list of <a href="#">roles</a>.</p> <p>For more information, see <a href="#">REVOKE</a>.</p>                                                                                                                                                                                                                                                                                                                                                                               |
| Role                  | <p>A collection of access privileges to the <a href="#">instance</a>. Roles are themselves a privilege that can be granted to other roles. This is often done for convenience or to ensure completeness when multiple <a href="#">users</a> need the same privileges.</p> <p>For more information, see <a href="#">CREATE ROLE</a>.</p>                                                                                                                                                                                                                                 |
| Rollback              | <p>A command to undo all of the operations performed since the beginning of a <a href="#">transaction</a>.</p> <p>For more information, see <a href="#">ROLLBACK</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                               |
| Routine               | <p>A defined set of instructions stored in the database system that can be invoked for execution. A routine can be written in a variety of programming languages. Routines can be <a href="#">functions</a> (including set-returning functions and <a href="#">trigger functions</a>), <a href="#">aggregate functions</a>, and <a href="#">procedures</a>.</p> <p>Many routines are already defined within PostgreSQL itself, but user-defined ones can also be added.</p>                                                                                             |
| Row                   | See <a href="#">Tuple</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Savepoint             | A special mark in the sequence of steps in a <a href="#">transaction</a> . Data modifications after this point in time may be reverted to the time of the savepoint.                                                                                                                                                                                                                                                                                                                                                                                                    |

For more information, see [SAVEPOINT](#).

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Schema              | <p>A schema is a namespace for <a href="#">SQL objects</a>, which all reside in the same <a href="#">database</a>. Each SQL object must reside in exactly one schema.</p> <p>All system-defined SQL objects reside in schema <code>pg_catalog</code>.</p> <p>More generically, the term <i>schema</i> is used to mean all data descriptions (<a href="#">table</a> definitions, <a href="#">constraints</a>, comments, etc) for a given <a href="#">database</a> or subset thereof.</p> <p>For more information, see <a href="#">Section 5.9</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Segment             | <p>See <a href="#">File segment</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Select              | <p>The SQL command used to request data from a <a href="#">database</a>. Normally, <code>SELECT</code> commands are not expected to modify the <a href="#">database</a> in any way, but it is possible that <a href="#">functions</a> invoked within the query could have side effects that do modify data.</p> <p>For more information, see <a href="#">SELECT</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Sequence (relation) | <p>A type of relation that is used to generate values. Typically the generated values are sequential non-repeating numbers. They are commonly used to generate surrogate <a href="#">primary key</a> values.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Server              | <p>A computer on which PostgreSQL <a href="#">instances</a> run. The term <i>server</i> denotes real hardware, a container, or a <i>virtual machine</i>.</p> <p>This term is sometimes used to refer to an instance or to a host.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Session             | <p>A state that allows a client and a backend to interact, communicating over a <a href="#">connection</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Shared memory       | <p>RAM which is used by the processes common to an <a href="#">instance</a>. It mirrors parts of <a href="#">database</a> files, provides a transient area for <a href="#">WAL records</a>, and stores additional common information. Note that shared memory belongs to the complete instance, not to a single database.</p> <p>The largest part of shared memory is known as <i>shared buffers</i> and is used to mirror part of data files, organized into pages. When a page is modified, it is called a dirty page until it is written back to the file system.</p> <p>For more information, see <a href="#">Section 19.4.1</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                   |
| SQL object          | <p>Any object that can be created with a <code>CREATE</code> command. Most objects are specific to one database, and are commonly known as <i>local objects</i>.</p> <p>Most local objects reside in a specific <a href="#">schema</a> in their containing database, such as <a href="#">relations</a> (all types), <a href="#">routines</a> (all types), data types, etc. The names of such objects of the same type in the same schema are enforced to be unique.</p> <p>There also exist local objects that do not reside in schemas; some examples are <a href="#">extensions</a>, <a href="#">data type casts</a>, and <a href="#">foreign data wrappers</a>. The names of such objects of the same type are enforced to be unique within the database.</p> <p>Other object types, such as <a href="#">roles</a>, <a href="#">tablespaces</a>, replication origins, subscriptions for logical replication, and databases themselves are not local SQL objects since they exist entirely outside of any specific database; they are</p> |

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                           | <p>called <i>global objects</i>. The names of such objects are enforced to be unique within the whole database cluster.</p> <p>For more information, see <a href="#">Section 22.1</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| SQL standard              | A series of documents that define the SQL language.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Standby (server)          | See <a href="#">Replica (server)</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Stats collector (process) | <p>This process collects statistical information about the <i>instance</i>'s activities.</p> <p>For more information, see <a href="#">Section 27.2</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| System catalog            | <p>A collection of <i>tables</i> which describe the structure of all <i>SQL objects</i> of the instance. The system catalog resides in the schema <code>pg_catalog</code>. These tables contain data in internal representation and are not typically considered useful for user examination; a number of user-friendlier <i>views</i>, also in schema <code>pg_catalog</code>, offer more convenient access to some of that information, while additional tables and views exist in schema <code>information_schema</code> (see <a href="#">Chapter 39</a>) that expose some of the same and additional information as mandated by the <i>SQL standard</i>.</p> <p>For more information, see <a href="#">Section 5.9</a>.</p> |
| Table                     | <p>A collection of <i>tuples</i> having a common data structure (the same number of <i>attributes</i>, in the same order, having the same name and type per position). A table is the most common form of <i>relation</i> in PostgreSQL.</p> <p>For more information, see <a href="#">CREATE TABLE</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Tablespace                | <p>A named location on the server file system. All <i>SQL objects</i> which require storage beyond their definition in the <i>system catalog</i> must belong to a single tablespace. Initially, a database cluster contains a single usable tablespace which is used as the default for all SQL objects, called <code>pg_default</code>.</p> <p>For more information, see <a href="#">Section 22.6</a>.</p>                                                                                                                                                                                                                                                                                                                    |
| Temporary table           | <p><i>Tables</i> that exist either for the lifetime of a <i>session</i> or a <i>transaction</i>, as specified at the time of creation. The data in them is not visible to other sessions, and is not <i>logged</i>. Temporary tables are often used to store intermediate data for a multi-step operation.</p> <p>For more information, see <a href="#">CREATE TABLE</a>.</p>                                                                                                                                                                                                                                                                                                                                                  |
| TOAST                     | <p>A mechanism by which large attributes of table rows are split and stored in a secondary table, called the <i>TOAST table</i>. Each relation with large attributes has its own TOAST table.</p> <p>For more information, see <a href="#">Section 70.2</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Transaction               | <p>A combination of commands that must act as a single <i>atomic</i> command: they all succeed or all fail as a single unit, and their effects are not visible to other <i>sessions</i> until the transaction is complete, and possibly even later, depending on the isolation level.</p> <p>For more information, see <a href="#">Section 13.2</a>.</p>                                                                                                                                                                                                                                                                                                                                                                       |
| Transaction ID            | <p>The numerical, unique, sequentially-assigned identifier that each transaction receives when it first causes a database modification. Frequently abbreviated as <i>xid</i>.</p> <p>For more information, see <a href="#">Section 8.19</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Transactions per second (TPS) | Average number of transactions that are executed per second, totaled across all sessions active for a measured run. This is used as a measure of the performance characteristics of an instance.                                                                                                                                                                                                                                                                                                          |
| Trigger                       | <p>A <a href="#">function</a> which can be defined to execute whenever a certain operation (INSERT, UPDATE, DELETE, TRUNCATE) is applied to a <a href="#">relation</a>. A trigger executes within the same <a href="#">transaction</a> as the statement which invoked it, and if the function fails, then the invoking statement also fails.</p> <p>For more information, see <a href="#">CREATE TRIGGER</a>.</p>                                                                                         |
| Tuple                         | A collection of <a href="#">attributes</a> in a fixed order. That order may be defined by the <a href="#">table</a> (or other <a href="#">relation</a> ) where the tuple is contained, in which case the tuple is often called a <i>row</i> . It may also be defined by the structure of a result set, in which case it is sometimes called a <i>record</i> .                                                                                                                                             |
| Unique constraint             | <p>A type of <a href="#">constraint</a> defined on a <a href="#">relation</a> which restricts the values allowed in one or a combination of columns so that each value or combination of values can only appear once in the relation — that is, no other row in the relation contains values that are equal to those.</p> <p>Because <a href="#">null values</a> are not considered equal to each other, multiple rows with null values are allowed to exist without violating the unique constraint.</p> |
| Unlogged                      | <p>The property of certain <a href="#">relations</a> that the changes to them are not reflected in the <a href="#">WAL</a>. This disables replication and crash recovery for these relations.</p> <p>The primary use of unlogged tables is for storing transient work data that must be shared across processes.</p> <p><a href="#">Temporary tables</a> are always unlogged.</p>                                                                                                                         |
| Update                        | <p>An SQL command used to modify <a href="#">rows</a> that may already exist in a specified <a href="#">table</a>. It cannot create or remove rows.</p> <p>For more information, see <a href="#">UPDATE</a>.</p>                                                                                                                                                                                                                                                                                          |
| User                          | A <a href="#">role</a> that has the <code>LOGIN</code> privilege.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| User mapping                  | <p>The translation of login credentials in the local <a href="#">database</a> to credentials in a remote data system defined by a <a href="#">foreign data wrapper</a>.</p> <p>For more information, see <a href="#">CREATE USER MAPPING</a>.</p>                                                                                                                                                                                                                                                         |
| UTC                           | Universal Coordinated Time, the primary global time reference, approximately the time prevailing at the zero meridian of longitude. Often but inaccurately referred to as GMT (Greenwich Mean Time).                                                                                                                                                                                                                                                                                                      |
| Vacuum                        | <p>The process of removing outdated <a href="#">tuple versions</a> from tables or materialized views, and other closely related processing required by PostgreSQL's implementation of <a href="#">MVCC</a>. This can be initiated through the use of the <code>VACUUM</code> command, but can also be handled automatically via <a href="#">autovacuum</a> processes.</p> <p>For more information, see <a href="#">Section 24.1</a> .</p>                                                                 |
| View                          | <p>A <a href="#">relation</a> that is defined by a <code>SELECT</code> statement, but has no storage of its own. Any time a query references a view, the definition of the view is substituted into the query as if the user had typed it as a subquery instead of the name of the view.</p> <p>For more information, see <a href="#">CREATE VIEW</a>.</p>                                                                                                                                                |

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Visibility map (fork)     | <p>A storage structure that keeps metadata about each data page of a table's main fork. The visibility map entry for each page stores two bits: the first one (<code>all-visible</code>) indicates that all tuples in the page are visible to all transactions. The second one (<code>all-frozen</code>) indicates that all tuples in the page are marked frozen.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| WAL                       | <p>See <a href="#">Write-ahead log</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| WAL archiver (process)    | <p>A process that saves copies of <a href="#">WAL files</a> for the purpose of creating backups or keeping <a href="#">replicas</a> current.</p> <p>For more information, see <a href="#">Section 25.3</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| WAL file                  | <p>Also known as <i>WAL segment</i> or <i>WAL segment file</i>. Each of the sequentially-numbered files that provide storage space for <a href="#">WAL</a>. The files are all of the same predefined size and are written in sequential order, interspersing changes as they occur in multiple simultaneous sessions. If the system crashes, the files are read in order, and each of the changes is replayed to restore the system to the state it was in before the crash.</p> <p>Each WAL file can be released after a <a href="#">checkpoint</a> writes all the changes in it to the corresponding data files. Releasing the file can be done either by deleting it, or by changing its name so that it will be used in the future, which is called <i>recycling</i>.</p> <p>For more information, see <a href="#">Section 29.7</a>.</p> |
| WAL record                | <p>A low-level description of an individual data change. It contains sufficient information for the data change to be re-executed (<i>replayed</i>) in case a system failure causes the change to be lost. WAL records use a non-printable binary format.</p> <p>For more information, see <a href="#">Section 29.7</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| WAL segment               | <p>See <a href="#">WAL file</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| WAL writer (process)      | <p>A process that writes <a href="#">WAL records</a> from <a href="#">shared memory</a> to <a href="#">WAL files</a>.</p> <p>For more information, see <a href="#">Section 19.5</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Window function (routine) | <p>A type of <a href="#">function</a> used in a <a href="#">query</a> that applies to a <a href="#">partition</a> of the query's <a href="#">result set</a>; the function's result is based on values found in <a href="#">rows</a> of the same partition or frame.</p> <p>All <a href="#">aggregate functions</a> can be used as window functions, but window functions can also be used to, for example, give ranks to each of the rows in the partition. Also known as <i>analytic functions</i>.</p> <p>For more information, see <a href="#">Section 3.5</a>.</p>                                                                                                                                                                                                                                                                       |
| Write-ahead log           | <p>The journal that keeps track of the changes in the <a href="#">database cluster</a> as user- and system-invoked operations take place. It comprises many individual <a href="#">WAL records</a> written sequentially to <a href="#">WAL files</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

# Appendix P. Color Support

Most programs in the PostgreSQL package can produce colored console output. This appendix describes how that is configured.

## P.1. When Color is Used

To use colored output, set the environment variable `PG_COLORS` as follows:

1. If the value is `always`, then color is used.
2. If the value is `auto` and the standard error stream is associated with a terminal device, then color is used.
3. Otherwise, color is not used.

## P.2. Configuring the Colors

The actual colors to be used are configured using the environment variable `PG_COLORS` (note plural). The value is a colon-separated list of *key=value* pairs. The keys specify what the color is to be used for. The values are SGR (Select Graphic Rendition) specifications, which are interpreted by the terminal.

The following keys are currently in use:

`error`

used to highlight the text “error” in error messages

`warning`

used to highlight the text “warning” in warning messages

`locus`

used to highlight location information (e.g., program name and file name) in messages

The default value is `error=01;31:warning=01;35:locus=01` (01;31 = bold red, 01;35 = bold magenta, 01 = bold default color).

### Tip

This color specification format is also used by other software packages such as GCC, GNU coreutils, and GNU grep.

---

# Appendix Q. Obsolete or Renamed Features

Functionality is sometimes removed from PostgreSQL, feature, setting and file names sometimes change, or documentation moves to different places. This section directs users coming from old versions of the documentation or from external links to the appropriate new location for the information they need.

## Q.1. `recovery.conf` file merged into `postgresql.conf`

Postgres Pro 11 and below used a configuration file named `recovery.conf` to manage replicas and standbys. Support for this file was removed in Postgres Pro 12. See [the release notes for PostgreSQL 12](#) for details on this change.

On Postgres Pro 12 and above, [archive recovery](#), [streaming replication](#), and [PITR](#) are configured using [normal server configuration parameters](#). These are set in `postgresql.conf` or via `ALTER SYSTEM` like any other parameter.

The server will not start if a `recovery.conf` exists.

The `trigger_file` setting has been renamed to [promote\\_trigger\\_file](#).

The `standby_mode` setting has been removed. A `standby.signal` file in the data directory is used instead. See [Standby Server Operation](#) for details.

## Q.2. Default Roles Renamed to Predefined Roles

PostgreSQL 13 and below used the term “Default Roles”. However, as these roles are not able to actually be changed and are installed as part of the system at initialization time, the more appropriate term to use is “Predefined Roles”. See [Section 21.5](#) for current documentation regarding Predefined Roles, and [the release notes for PostgreSQL 14](#) for details on this change.

## Q.3. `pg_xlogdump` renamed to `pg_waldump`

Postgres Pro 9.6 and below provided a command named `pg_xlogdump` to read write-ahead-log (WAL) files. This command was renamed to `pg_waldump`, see [pg\\_waldump](#) for documentation of `pg_waldump` and see [the release notes for PostgreSQL 10](#) for details on this change.

## Q.4. `pg_resetxlog` renamed to `pg_resetwal`

Postgres Pro 9.6 and below provided a command named `pg_resetxlog` to reset the write-ahead-log (WAL) files. This command was renamed to `pg_resetwal`, see [pg\\_resetwal](#) for documentation of `pg_resetwal` and see [the release notes for PostgreSQL 10](#) for details on this change.

## Q.5. `pg_receivexlog` renamed to `pg_receivewal`

Postgres Pro 9.6 and below provided a command named `pg_receivexlog` to fetch write-ahead-log (WAL) files. This command was renamed to `pg_receivewal`, see [pg\\_receivewal](#) for documentation of `pg_receivewal` and see [the release notes for PostgreSQL 10](#) for details on this change.
